The immediate effects of occlusion of a large branch of the coronary arteries may be extreme dilatation and failure of the heart. The part supplied by the occluded vessel becomes infarcted, and if the patient survives, the whole area eventually becomes fibrotic. The early dilatation to a large degree disappears, but if the infarcted area is large, hypertrophy of varying degrees takes place. Recently Smith and Bartels¹⁰ cited two cases of extensive coronary occlusion in which the heart weights were greatly

increased, there was enormous dilatation without much increase in thickness of the ventricular walls. These authors followed this report with a much larger series of 42 cases⁴¹ of coronary occlusion from which all other possibilities of hypertrophy had been eliminated. They calculated the normal heart weights by Smith's method and found a definite increase in weight of from 9 per cent to 108 per cent in 37 of the 42 cases, the actual weights varying between 265 and 715 grams. The average increase in weight above the calculated normal for the whole group was 44 per cent. From this study they concluded that coronary occlusion with cardiac infarction was a definite cause of hypertrophy.

There were five cases of coronary occlusion in our series in which there was neither history nor evidence of hypertension at the time of admission to the hospital. In addition there were four other cases of coronary occlusion with definite hypertension which were included under the heading "Hypertension with Other Complications."

Although all these hearts were very definitely above the normal weight (average 518 grams), it is difficult to draw conclusions from so small a group. A previous hypertension is almost impossible to exclude, since some of the patients were in a condition of shock on entering the hospital. The myocardial changes consisted of hypertrophy and of old or recent infarcts. The electrocardiographic changes, left axis deviation, bundle branch block, and altered QRS and T-waves are consistent with recent and old coronary occlusion and with hypertension.

5 CONGENITAL HYPERTROPHY OF THE HEART

According to Kugel and Stoloff⁴⁴ only 52 cases of congenital idiopathic hypertrophy of the heart had been reported up to 1933, in addition to the seven which they reported in April of that year. These authors consider that only those cases which show pure hypertrophy of the muscle fibers should be considered as idiopathic hypertrophy, and that if such changes as fibrosis or any kind of degeneration are present, the heart cannot then be said to be an example of idiopathic hypertrophy. Using this standard they found that only 17 out of 59 cases had "true idiopathic hypertrophy," the remaining cases showing changes secondary to some other process.

Many different causes for congenital hypertrophy of the heart have been suggested, but no one has been found to be operative in a considerable number of individuals. In one of our cases, which has already been reported,⁴⁵ glycogen storage (von Gierke's) disease was later found responsible, and there was a very unusual family history in that several members of the family had cardiac defects, thus suggesting the probability of an inheritance of a tendency to this cardiac anomaly. Bland, White, and Garland⁴⁸ have recently reported the case of a male infant dying at the age of three months, in whom at autopsy the left coronary artery arose from the pulmonary artery and the enlarged heart showed much disease of the left

ventricular myocardium, eight similar cases had been previously reported. Other possible etiological factors which have been mentioned as causes of cardiac hypertrophy in infancy besides congenital septal and valvular defects are infection, hypertension in the parents, enlarged thymus, and congenital medial sclerosis.

There were four cases of congenital hypertrophy in our series. In the first three this diagnosis was made clinically, while in the last the case was regarded as one of cardiac hypertrophy of unknown origin in an infant.

In our four cases the weight of the hearts was increased from two to six times the normal. Two of the hearts were described as dilated, one as enlarged, and one as enlarged with right ventricular hypertrophy and petechial hemorrhages over the left ventricular base. Microscopic changes were unimportant except for hypertrophied and vacuolated fibers in one of the cases. One case died of congestive failure, one of congestive failure and bronchopneumonia, one at birth, while the immediate cause of death in the fourth was uncertain.

6 HYPERTHYROIDISM

There has always been a division of opinion as to whether hyperthyroidism per se produces definite myocardial abnormalities, or whether the cardiac pathological changes are the result of increased metabolism. Recently Rake and McEachern⁵⁴ examined the hearts of 27 autopsied cases of hyperthyroidism, and, by comparing the results with those from supposedly normal hearts of similar age groups, found only five of the 27 with changes more marked than in the controls. Muscular scarring, perivascular fibrosis, cellular infiltration, and altered staining reactions were reported in the five cases noted above, with lesser degrees of the same findings in many others. The writers considered the picture to be merely an accentuation of normal katabolic changes brought on by the increased metabolic and cardiac activity and in no way peculiar to the hyperthyroid state. Kepler⁵⁰ studied 57 cases of exophthalmic goiter and 16 cases of toxic adenoma from the point of view of hypertrophy of the heart and found that 49 per cent of them showed an increase in weight when compared with the Smith standards. The body weights used in the calculations were those prior to the onset of the condition. Burnett and Durbin⁵² found evidence of definitely abnormal axis deviation in 24 of 62 patients—right in 7 and left in 17.

There were nine cases with the clinical diagnosis of hyperthyroidism which came to autopsy over this period. In seven of them the heart was described as normal. In the other two, one of them complicated by a moderate hypertension, the heart weight was moderately increased though the myocardium was apparently normal. The "bile staining," noted in one of them, was a part of a general icterus, while the rather high systolic pressure was probably secondary to the thyrotoxicosis rather than of the essential variety.

7 CARDIAC FAILURE OF UNCERTAIN ETIOLOGY

A few years ago Christian ³⁸ pointed out that there are a large number of cases of cardiac failure occurring in middle age for which there is no obvious reason. He stated that although arteriosclerosis, coronary disease, previous acute infections, or previous hypertension may account for some, yet in many no etiological agent is apparent. Clinically there is evidence of muscular deficiency, but physical examination and electrocardiographic studies may be entirely negative. Pathologically the hearts are often hypertrophied and may or may not show fibrosis.

There were eight cases in our series which seemed to fall into this group. In three of them there was a strong possibility of a previous hypertension, although the pressures recorded did not justify inclusion in that group.

Of these cases all except two were in the very upper limits of our age group. Cardiac enlargement, in two cases of marked degree, was noted in six instances. Failure to record the blood pressure in three cases naturally makes exclusion of hypertension impossible, while a marked anemia in another may well have been an etiological factor. Myocardial changes consisted of dilatation, hypertrophy, and gross and microscopic scarring. Electrocardiograms gave evidence of disturbed conduction, either in the bundle or in the ventricular muscle.

One of the cases (case 8 in the tables) is of particular interest because of the youth of the patient. On his first entry to the hospital he presented the picture of cardiac decompensation which was considered to be probably on a rheumatic basis, although no specific history was obtained. After a few weeks in the ward he was discharged greatly improved to a convalescent home where he remained off and on for eight months. At that time his symptoms returned and he reentered the hospital where he died in a short time. Autopsy did not explain the cause of his cardiac failure. Somewhat similar cases of idiopathic cardiac hypertrophy have recently been reported by Levy ⁴³

8 MISCELLANEOUS

Seventeen cases were of so varied a nature that they have been placed in a miscellaneous group. The diagnoses in this group include generalized malignancy 5, brain tumor 3, cirrhosis of the liver 2, rhabdomyoma 1, ruptured aortic aneurysm 1, gastric ulcer with hemorrhage 1, thrombosis of portal vein 1, nephrosis 1, enlargement of liver and spleen of unknown cause 1, and pregnancy and labor 1.

Of the five cases of generalized malignancy, four showed definite increase in heart weight with metastatic involvement of the myocardium in two. Cardiac enlargement was observed in all three cases of intracranial tumor and in one of them there was malignant involvement of the heart muscle. The largest heart in this group was associated with cirrhosis of the liver and luetic aortitis, it was impossible to tell if either factor was really connected with the hypertrophy. In the case of uncomplicated cir-

rhosis the enlargement was not so striking. In the remaining seven cases increase in heart weight was noted in six, and, with the exception of two cases, for no very obvious reason. In one case the myocardium was riddled with a rhabdomyoma, nodules of which partly occluded two valves, while in another, a 6 year old boy, degenerative changes in the myocardium were found with general glandular enlargement of unknown etiology. In the one case of nephrosis (case 15) the weight was well within normal limits, but atrophy and fatty infiltration of the myocardium were reported.

Although it is impossible to draw any conclusions from so varied a group, yet the frequent association of cardiac hypertrophy with malignancy is difficult to explain, except where metastatic involvement occurred. There was no marked degree of anemia in any of these cases, nor was there any other apparent cause of enlargement.

SUMMARY

An analysis has been made by us of 250 instances of myocardial abnormality in individuals under the age of 46 years without valvular disease or congenital defects found among 4,531 cases examined post mortem at the Massachusetts General and Boston City Hospitals.

There were 97 cases with hypertension in which the chief cardiac lesion was hypertrophy with diffuse or perivascular fibrosis in about 40 per cent.

There were 91 cases of acute and chronic infections in which cardiac abnormalities were observed. In acute pulmonary infections hypertrophy of the heart was frequently noted with dilatation, edema of the muscle, and occasionally focal necroses. In the chronic pulmonary infections generalized or right ventricular enlargement was noted in several cases without characteristic microscopic changes. In acute infections other than pulmonary, there occurred severe muscle damage in diphtheria, focal necroses frequently in severe toxemias, and occasional milary abscesses in extensive pyemias. In chronic infections other than pulmonary there was often moderate increase in heart weight with myocardial fibrosis in some cases.

There were 27 cases of various blood dyscrasias in which hypertrophy was noted in less than half, with microscopic changes consisting of fatty infiltration, slight fibrosis, petechial hemorrhages, and leukemic infiltration.

Nine cases of coronary thrombosis, five complicated by known hypertension, showed marked hypertrophy with recent or old infarction.

In four cases of congenital cardiac hypertrophy in infants, there was marked increase in heart weight with negligible microscopic changes except for hypertrophy and vacuolization of muscle fibers in one case.

In two cases of hyperthyroidism, one complicated by systolic hypertension, there was moderate cardiac enlargement without significant microscopic changes.

In eight cases of cardiac failure of uncertain etiology, hypertrophy and myocardial fibrosis were the most important lesions.

In seventeen miscellaneous cases no constant changes were observed, though the association of myocardial abnormalities with generalized and intracranial malignancy in several cases was interesting

We wish to express our thanks to Dr Paul D White for his never-failing aid in the assembling and critical analysis of our material. It was at his suggestion that this study was begun and it was through him that it finally reached its present form. We wish also to acknowledge the courtesy and cooperation of the Pathological Departments of the Massachusetts General and Boston City Hospitals in granting permission to use their material

THE SIGNIFICANCE OF SPECIFIC PNEUMOCOCCUS TYPES IN DISEASE, INCLUDING TYPES IV TO XXXII (COOPER) ^{*}

By MAXWELL FINLAND, M D , *Boston, Massachusetts*

THE recent increase in the use of specific serum for the treatment of pneumonia has been accompanied by a growing interest in the newer types of pneumococci ¹ in many parts of this and other countries. It seems appropriate, therefore, to present a brief résumé of 3682 cases admitted to the Boston City Hospital, from which pneumococci were cultured and typed with the aid of serums for these new types. Approximately one-third of these cases, previously reported,² occurred before June 1, 1932 and were typed with serums for Types I to XX. The remaining cases were admitted before July 1, 1936 and were typed with serums for Types I to XXXII, inclusive.

PATIENTS, SOURCES OF PNEUMOCOCCI, AND METHODS

These are described in previous papers ³ in which selected groups of cases were analyzed in considerable detail. The serums used in the classification of pneumococci Types IV to XXXII were obtained through the generosity of Dr. William H. Park and the late Miss Georgia Cooper of the Bureau of Laboratories of the New York City Department of Health. The bacteriologic and pathologic data were made available through the kindness of Dr. Frederick Parker, Jr. and Dr. Robert N. Nye of the Mallory Institute of Pathology of the Boston City Hospital. To them, to the resident and visiting staffs of the Boston City Hospital, and to the physicians and laboratory assistants who, at different times, participated directly in this study, the author acknowledges his gratitude.

ANNUAL AND MONTHLY INCIDENCE OF THE VARIOUS PNEUMOCOCCUS TYPES

The total number of cases of pneumococcic infections varied considerably from year to year (table 1) [†]. The annual incidence of some of the individual pneumococcus types fluctuated even more widely. Noteworthy is the sharp increase in the number of cases of infection with Types II, V and VII pneumococci during the 1935 to 1936 season. The mortality also varied in different seasons ^{§c, d}.

* Received for publication January 26, 1937.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston, Mass.

This study was aided, in part, by a grant given in memory of Francis Weld Peabody by the Ella Sachs Plotz Foundation.

† In the tables, the Types XXVI and XXX have been omitted. The former is probably identical with Type VI and the latter is either closely related to or identical with Type XV. Type XXX was identified in two cases, one with lobar pneumonia, the other with a common cold, these are included with the Type XV cases.

The month of greatest incidence of all pneumococcic infections was always one of the winter months (January to March), but it varied in different years. While the peak of incidence was usually the same for most of the common types, disproportionate increases occurred at various times for individual types.^{3b}

OCCURRENCE OF SPECIFIC PNEUMOCOCCUS TYPES IN DIFFERENT DISEASES

All of the cases with typed pneumococci were divided into six groups and the number and percentage of cases of each type occurring within each category are given in table 2. All patients over 12 years of age are listed as adults. The groups may be described briefly.

A Under *lobar pneumonia* are included all cases with uniform consolidation in one or more lobes of the lung according to the best evidence obtainable from pathological, roentgenological, or physical examination. In

table 2, the cases in which there was additional patchy or atypical solidification in other parts of the lung were included in this category. The most frequent types in this group were Types I, III, II, V, VIII, and VII, in the order named. These six types together accounted for 79 per cent of the cases of lobar pneumonia.

* Includes cases with lobar pneumonia in one or more lobes and atypical in other parts.

† Some of the cases previously included (2) have been omitted because of insufficient data to classify the organisms as pneumococci.

B All cases with patchy or with peribronchial pulmonary consolidation were included as *atypical pneumonia*,⁴ a designation used throughout this paper instead of the term "bronchopneumonia" The most frequent types in these cases were Types III, VIII, X, XX, XVIII, and VIII which, together, accounted for one-half the cases of this group

The pneumococcus types in the cases of pneumonia in adults (groups *A* and *B*) were obtained from cultures of either sputum, blood, lung, infected exudates or autopsy material, or from more than one of these sources In about half the cases the sputum was the only source

C Cases of *adults with empyema* present at the time of admission, in which the pneumococcus type was obtained from the infected pleural exudate, are listed separately The types most frequent in this group were the same, except for order, as among the cases of lobar pneumonia in adults, namely Types I, II, VIII, III, V, and VII, which accounted for 84 per cent of the group

D Most of the cases of *pneumonia in children*, with or without empyema, were typed either from pleural exudate or from material obtained at autopsy In occasional cases, the pneumococci were obtained from blood cultures or, more rarely, from sputum or throat cultures About two-thirds of these cases had empyema Type I alone accounted for more than half of the cases Types V, XIV, II, VI and III, respectively, ranked next in frequency These six types included 82 per cent of the cases of this group

E Under *focal infections* are included cases in all age groups in which the pneumococci were cultured from the infected focus and in which there was no evidence of pneumonia at the time Type III organisms were most frequent in this group, with Types I, VIII, II, and V following in the order named Together, these five types included slightly more than one-half the cases in this category

F The last group includes cases of *acute or chronic respiratory infections* where there was no evidence of pneumonia attributable to the pneumococcus This group also includes cases that may be termed *carriers*, in whom the pneumococci were obtained from routine nasal, pharyngeal, or sputum cultures taken during the course of other diseases and in whom there was no evidence of infection attributable to the pneumococcus In this group, Types III, XVIII, VII, VI, VIII, X, and XX were most common, in that order, these seven types constituting more than half of the total

CASES WITH AUTOPSY

In 764 of the fatal cases there was an opportunity to ascertain at necropsy the relationship of the pneumococcus to the infection The classification of the autopsied cases according to the pneumococcus type, with particular reference to the character of the pulmonary lesion in the cases with pneumonia, is given in table 3 The six most frequent types in the cases with lobar pneumonia were the same, in essentially the same order, as noted in

table 2, namely, Types I, III, II, V, VII, and VIII, these types accounting for 83 per cent of the cases. One-sixth of all the cases that had lobar pneumonia at autopsy also showed some areas of atypical consolidation in other portions of the lung.

TOTALS	339	100	290	100	55	62	18	764	100

Among the cases in which only atypical pneumonia was found in the lungs at autopsy, Types I and V ranked high in incidence, in addition to the types noted previously for the entire group. The most common types among these cases, in the order of their frequency were Types III, VIII, V, I, X, VI, VII, XX, and XVIII, these nine types including 68 per cent of the total. The discrepancy between the relative frequency in the entire group and in the autopsied cases is explicable on the basis of differences in mortality rates, as will be noted below.

* These include the following

Endocarditis 3 cases (Types I, VIII and X, 1 each),

Purulent arthritis 3 (Types I, XII, XIV, 1 each),

Osteomyelitis 7 (Type II, 2 cases, Types I, VIII, XI, XIX, XXII, 1 each),

Acute sinusitis 6 (Types II and VIII, 2 each, Types I, VI, 1 each),

Pulmonary abscesses 4 (Types III and V, 2 each),

Subcutaneous abscesses 10 (Type III, 3, Types II and XI, 2 each, and Types VII, VIII and XIV, 1 each),

Puerperal sepsis 3 (Type I, 2 and Type VIII, 1),

Bacteremia (positive blood culture, source not discovered) 18 (Types I and VIII, 4 each, Types II and III, 3 each, Types IV, VI, XI and Neg I to XX, 1 each)

Also one case each of Pericarditis, Type I, Infected hemothorax, Type I, Acute cystitis, Type III, Acute cholecystitis, Type III, Peritonsillar abscess, Type III, Mediastinitis, Type III, Subphrenic abscess, Type III, and Ulcerative colitis, Type IV

† The following are not listed

Arthritis 8 cases (Type I, 5, Type II, 1 and Type III, 2),

Parotitis 6 (Type I, 4, Types II and III, 1 each),

Conjunctivitis 4 (Type II, 1, Type III, 2, Type VIII, 1),

Liver abscess 1 (Type XI)

Empyemas in children and those present on admission in adults are listed in table 2 (D and B)

FOCAL PURULENT PNEUMOCOCCIC INFECTIONS

The numbers of cases in which each of the various types of pneumococci were cultured from focal infections, including those complicating pneumonia, are shown in table 4. Middle ear and mastoid infections were the most common in the cases without pneumonia, the Type III pneumococcus being the causative organism in about half of these cases. Meningitis, with or without middle ear or mastoid infection, was next in frequency and peritonitis ranked third. Of interest are the 18 cases of bacteremia, mentioned in the footnote to the table, in which neither pneumonia nor purulent foci were found even at the autopsy, which was performed in almost all of these cases.

Among the cases of pneumonia in adults, empyema was the most frequent purulent complication. Type I was most frequent in these cases as it was in the empyemas of children and in the adults who had empyema at the time of admission to the hospital (table 2). Lung abscesses or focal areas of necrosis were next in frequency, the most common organism being the Type III. Almost all of these were first observed at autopsy and a large proportion were seen only in the microscopic sections. The pneumococci in the latter cases were obtained from the infected lung. Pericarditis ranked third in frequency and, like endocarditis, was usually diagnosed at autopsy.

PNEUMONIA IN ADULTS

The percentage of incidence and of mortality among the pneumonias caused by the more frequent of the pneumococcus types is analyzed in table 5 with respect to three important features, each of which may be considered separately.

Lobar Pneumonia and Atypical Pneumonia There were cases of lobar pneumonia and of atypical pneumonia due to almost every one of the pneumococcus types (table 2). About one-fifth of all the cases of pneumococcus pneumonia had only atypical pulmonary consolidation. Types I and II stand out from among all the others as causing typical lobar pneumonia with the greatest regularity. Only 4 and 5 per cent of the cases of pneumonia due to these types, respectively, had only atypical involvement, and an additional smaller number of cases with lobar pneumonia due to these types had atypical consolidation in other portions of the lung. Among the other frequent types, more than two-thirds of the cases due to Types III, IV, V, VII, IX, XII, and XIV were lobar pneumonia, whereas about one-half of those caused by Types VI, X, XVII, XVIII, XX, and those with higher type designations were atypical.

The mortality was considerably higher among the cases with atypical pneumonia. This was true for all the cases, as well as for the cases within each type, the only exceptions being those with the Type III pneumococcus. Bacteremia was only half as frequent among the cases with atypical pneumonia as among those with lobar pneumonia. On the other hand, almost

* Specific types are listed separately when there were more than 30 cases of pneumonia

† Including cases in which the pneumococcus failed to agglutinate in sera of Types I to XX or I to XXXII

‡ Calculated on the basis of patients having blood cultures made

two-thirds of the former cases were secondary to other serious illnesses, as compared with only 10 per cent of the latter. The higher mortality among the cases with atypical pneumonia, therefore, is probably attributable to factors within the host rather than to difference in virulence of the organism. The much greater frequency of atypical pneumonias in persons over 70 years of age (17 per cent of all the atypical cases as compared with 5 per cent of the lobar pneumonias) lends further support to this view.

"Secondary" Pneumonia As in previous studies,³ cases occurring as terminal events or as acute episodes in the course of other serious illness and those complicating parturition, the puerperium, surgical operations, or other serious acute infectious diseases were called "secondary." All other cases, including those with antecedent simple infections of the upper respiratory tract, "grippe," influenza, or bronchitis were called primary. Among the cases with atypical pulmonary involvement, the secondary pneumonias were more than six times as frequent as among the cases with lobar consolidation. The mortality was about twice as great among the secondary as among the primary pneumonias. The greater incidence of secondary pneumonias thus serves to explain the greater mortality among the cases of atypical pneumonia.

Bacteremia The percentage of cases of pneumonia in which pneumococci were cultured from the blood varied with the different types. Bacteremia was much less frequent among the cases with atypical pneumonia than among those with lobar pneumonia. In general the mortality among the cases of lobar pneumonia corresponded to the incidence of bacteremia,⁵ but this was not true for all the types of pneumococci. The mortality among the bacteremic cases was uniformly higher, and averaged about twice as high as among those with sterile blood cultures. This was true irrespective of the character of the pulmonary lesion.

Serum treatment was carried out almost exclusively in cases of lobar pneumonia due to Types I, II, V, and VII. Only the gross mortalities are given here and indicate a reduction to about one-half the mortality in non-serum treated cases. The results of serum therapy in these cases are presented in greater detail in other publications.^{3a, 6}

Age Incidence The highest incidence of lobar pneumonia occurred in the fourth and fifth decades of life, declining rapidly thereafter, in the atypical pneumonias the peak was in the sixth decade and there was almost no decline in the next two decades. Among the cases of lobar pneumonia of the more common types, those due to Types II, V, and VII each showed their highest incidence in the fourth decade. Those due to Type III had a peak of incidence among the cases in the sixth decade of life, while the cases of Types I and VIII pneumococcus lobar pneumonia were most prevalent in the fifth decade.

MIXED INFECTIONS

There were 424 cases of pneumonia in which, in addition to the pneumococcus of the type under which the case was classified, other pathogenic organisms were obtained. These were cultured from sputum or from other

* 1 case had pneumococci of 2 other types

sources during the acute illness, early in convalescence or at autopsy. Pyogenic organisms other than pneumococci, when obtained from sputum, were listed only when they were predominant in a good specimen or when they were cultured from the heart's blood of an injected mouse. Only hemolytic

strains of *Staphylococcus aureus* were included. Tubercle bacilli were noted whenever they were recognized in stained smears of sputum or pulmonary exudate. The number of cases in which various organisms were obtained in the pneumonias due to the various pneumococcus types is shown in table 6.

In 103 cases multiple pneumococcus types were isolated, five of these cases yielding three distinct types. The most frequent other organisms were *Beta hemolytic streptococcus*, *Hemophilus influenzae*, *Staphylococcus aureus hemolyticus*, *Streptococcus viridans*, and *Bacillus mucosus capsulatus* (Friedlander), in that order. Occasional instances of focal infections with colon bacillus, *Bacillus welchii*, or other organisms were noted as complicating the pneumococcus pneumonia. In other cases, the pneumococcus pneumonias occurred as a complication of other infections during which the causative agent, notably typhoid and paratyphoid bacilli were cultured.

The number of cases of pneumonia in which each of the various pneumococcus types occurred as a mixed infection, is also shown in table 6. The last column gives the distribution of types among 24 instances in which two types of pneumococci were identified among cases without pneumonia.

The significance of the various organisms in cases of pneumonia with mixed infection varies with each case. This has been discussed elsewhere.⁷

COMMENT

Type-specific antipneumococcic serum, within its limitations, is the only curative agent thus far recommended for the treatment of pneumonia which has stood the tests of experience, experiment, and critical analysis. The extension of serological typing to include practically all strains of pneumococci,¹ and the studies of the prevalence of these new types in health⁸ and disease,^{1, 2, 9} in addition to its great importance for the better understanding of the clinical, immunologic, and epidemiologic features of pneumococcic infections, has already proved useful in extending the field of specific serum therapy and holds promise for further practical benefits. Bullowa¹⁰ has reported favorable results in the treatment of cases of pneumonia due to Types VII, VIII, XIV, and V pneumococci, and equally promising results were observed in the treatment of small groups of cases of Type V and Type VII pneumococcus pneumonia in this clinic.^{6a, e}

It was not possible, in the space available, to analyze the material in any greater detail or to discuss the many possible implications of the findings recorded. Some of the clinical features of the more common types³ and the details of specific therapy⁶ in the present cases have been considered elsewhere. Other features of selected groups of cases, as well as the comparative significance of organisms other than the pneumococci⁷ are left for separate consideration. It is hoped that the material here presented will help somewhat in the orientation of those interested in this rather extensive field of pneumonia and pneumococcic infections.

SUMMARY

A series of 3682 cases is presented from which specific types of pneumococci were obtained and classified with the aid of the newer serums of Cooper¹. These cases occurred at the Boston City Hospital between November 1929 and June 30, 1936.

The incidence of the various types in different seasons and in different diseases and particularly in lobar pneumonia and atypical pneumonia (bronchopneumonia) is indicated.

The mortality rates in the cases of pneumonia in adults is noted with respect to (1) The type of infecting pneumococcus, (2) the character of the pulmonary lesion, (3) the presence of bacteremia, (4) the presence of other serious illness (secondary pneumonias), (5) serum therapy.

The incidence of mixed infections with pneumococci and other significant organisms is shown.

AN OUTBREAK OF TRICHINIASIS IN CENTRAL OHIO AND THE USE OF THE BACHMAN INTRADERMAL SKIN TEST

By AUGUSTUS A. HALL, M.D., *Columbus, Ohio*

THE infrequency with which trichiniasis is recognized in man restricts the opportunity to study this disease and makes it important to utilize all cases whenever possible for the investigation of the Bachman intradermal test.

The consumption of raw or inadequately cooked meat is more common in this country than is generally appreciated. While this is often done inadvertently, there are many who, from choice, eat raw sausages or other forms of pork deliberately, and these individuals constitute the majority of the more severe cases of trichiniasis.

The discovery and development of our knowledge of human trichiniasis has been reviewed recently, notably by McDonald,¹ and this will not be discussed here.

In the state of Ohio trichiniasis is not rare, although it is not often recognized. Doran² states that only two cases have appeared at St. John's Hospital, Cleveland, Ohio, in the past 16 years. At Grant Hospital, Columbus, Ohio, we could find records of only one case since 1925. The disease has been reportable to the Ohio State Department of Health since August 1928. From this date until March 1936, 96 cases have been reported, and of this number eight have died, a mortality of 8.33 per cent. The distribution of these cases is recorded in table 3.

Relatively few reports concerning the use of the Bachman test are to be found in the literature, in spite of the fact that Bachman³ first described the method in 1928. As late as 1931 an epidemic was reported in Pennsylvania by Aldridge⁴ with no mention of the test.

Bachman describes the preparation of his antigen thus: "The larvae are separated by artificial digestion and thoroughly washed free from host proteins—dried at 47° C. in a vacuum oven over sulphuric acid and thoroughly pulverized. Test antigen is prepared from a 1 per cent suspension of the dried pulverized trichinella powder extracted at room temperature for a day or longer in Coca's solution—then centrifuged at high speed for 15 minutes and the supernatant fluid used as the test antigen."

The powdered trichinella material is not available commercially at the present time.†

The antigen we used was prepared at Grant Hospital by O. H. Lausa. His technic was as follows: "Take 5 mg. of the dried trichinella powder

* Received for publication June 20, 1936.

† We wish to thank Dr. Benjamin Schwartz of the United States Department of Agriculture for supplying the necessary material.

Add 5 c c of Coca's solution and allow to stand at room temperature for 24 hours Then filter through a Berkefeld filter Culture to test for sterility Place in vaccine ampoules for use" The pH was about 8

CASE REPORTS *

These cases will be divided into two sections The first section will comprise the epidemic group, the second will be individual cases occurring at the same time in Columbus with different sources of infection

TABLE I
Data on Cases of Diagnosed Trichiniasis

Case	Ingestion of pork	Onset of symptoms	Eosinophilia		Bachman Intradermal Test		
			Admission	10 days later	1-1000	1-10,100	Control

SECTION I

About December 20, 1935, a 300 pound hog was butchered by a packing company in central Ohio. The meat was inspected and passed by an inspector. All of the cases to follow in this section ate the pork in a raw state prior to December 25, 1935 except C M who continued to eat it up to January 10, 1936 cooked "very rare."

Case 1 Mr C M, a white male 22 years of age, whose occupation was dairyman, was admitted to University Hospital on January 11, 1936 complaining of generalized malaise, pain in the back, fever and sweating.

Physical examination revealed edema of the eyelids, bilateral conjunctivitis and photophobia. There was marked generalized muscular pain, but other than this the physical examination was essentially negative. His temperature upon admission was 104.2° F, pulse 115, and respirations 38. A blood count revealed hemoglobin 85 per cent, erythrocytes 4,820,000, leukocytes 16,450, 67 segmented, 16 band, 10 lymphocytes, 2 monocytes, and 5 eosinophiles.

Biopsy of the gastrocnemius muscles near the tendinous attachment revealed severe myositis and larvae of *Trichinella spiralis*.

During the course of his stay in the hospital the leukocytes varied between 10,800 and 19,750. The highest eosinophile count was 31 per cent, and it is significant to note that the highest eosinophile counts were noted with the lowest total counts. Agglutination tests for typhoid fever, undulant fever, and tularemia were negative. The cerebro-spinal fluid was normal.

Treatment was symptomatic except for the use of neoarsphenamine which had no apparent effect. The patient was discharged from the hospital February 4, 1936 apparently in good condition except for considerable loss in weight.

Case 2 E B, a white female 27 years of age, was admitted to St Francis Hospital on January 14, 1936 complaining of severe pain in all the extremities, fever, diarrhea, generalized edema and sore throat.

About two weeks previous to admission she had eaten some raw pork and two or three days later first noticed a diarrhea. This continued for several days, and then she became constipated. The patient then developed severe muscular pains in all extremities with accompanying generalized edema, particularly under the eyes. She also had laryngitis which persisted for a few days. No glandular enlargement or swelling, and no vomiting were noted.

The physical examination revealed a white female, acutely ill and prostrated, with marked edema of legs and arms. The skin was anemic, dry and hot. There was marked edema under the eyelids. The throat was much injected and dysphagia pronounced. The heart was normal except for a rapid rate.

On admission her eosinophiles were 70 per cent, and 10 days later, 43 per cent.

Case 3 L E, a white male 30 years of age, was admitted to St Francis Hospital on January 14, 1936. Several weeks previous to admission he had eaten some raw pork. Soon after this he became quite ill and began to have diarrhea. He took a dose of epsom salts, and soon the symptoms began to subside, although edema of the eyelids developed. Diarrhea stopped and constipation was noted. Muscular pains were moderately severe. No nausea, vomiting, or cough.

Physical examination revealed a white male, not acutely ill and in no apparent distress. The skin was negative except for slight redness and edema of the eyelids. Examination was otherwise negative.

On admission his eosinophile count was 33 per cent, 10 days later it was 57 per cent.

Case 4 R B, a white boy eight years of age, was admitted to St Francis Hospital on January 14, 1936. This child ate some raw pork with other members of the family several weeks previous to admission. He became acutely ill, with cramps, diarrhea, and generalized edema. Severe muscular pains were present.

Physical examination revealed a white male child, apparently acutely ill with some evidence of prostration. The skin was negative. The eyes were negative except for slight edema of the eyelids. The examination was otherwise negative.

On admission the patient had 51 per cent eosinophiles, 10 days later they were 20 per cent.

Case 5 M T, a white female 24 years of age, was admitted to St Francis Hospital on January 14, 1936. At this time her temperature was 103° F (rectal) and she complained of pain in the extremities. She gave a history of having eaten raw pork about two weeks previous to her admission to the hospital. Shortly after, she began to develop intestinal symptoms followed by diarrhea. This was soon checked. The patient then developed edema of the eyelids but was relatively free from edema elsewhere. Pains were not particularly severe. She had no nausea or vomiting. She had had a mild fever for two weeks previous to admission.

Physical examination revealed a white female, apparently in no great distress, showing some puffiness of the eyelids. The skin was pale and anemic. The eyelids were slightly edematous with an area of redness around the orbit. Otherwise negative.

On admission she had an eosinophilia of 47 per cent, 10 days later it was 67 per cent.

Case 6 E T, a white female child three years of age, was admitted to St Francis Hospital on January 14, 1936 with pain in the extremities, edema, and fever.

The history was similar to those of the cases above. She developed edema of the eyelids, some diarrhea with occasional vomiting, and a fever of 103° F, rectal.

Physical examination revealed a white female child, acutely ill, and somewhat dehydrated, who apparently had had a high fever for some time. The eyelids showed some evidence of edema. The abdomen was slightly rigid, somewhat tympanic, slightly tender over the spleen and liver. Otherwise negative.

On admission she had an eosinophilia of 21 per cent, 10 days later the count was 32 per cent.

SECTION II

Case 1 C H, a white male 22 years of age, was admitted to University Hospital, January 24, 1936, complaining of swelling of the eyelids, generalized muscular weakness and malaise. The patient gave a history of having eaten improperly cooked hamburgers frequently during the past six months or year. The present symptoms appeared seven days prior to admission. He also complained of nausea, vomiting, diarrhea, and a conjunctivitis. He was seen at the Student Health Service on the campus of Ohio State University and was referred to the hospital with a diagnosis of trichiniasis.

Upon admission the eosinophile count was 72 per cent. His temperature was 102.4° F.

Case 2 G R, a white female 12 years of age (author's case), gave a history of having eaten some rare roast pork (purchased from a chain grocery store) about January 5, 1936, and a day or so afterwards she ate some rare side meat of pork from the same source. About January 14 she first noticed that her eyelids were markedly swollen, especially in the morning. They seemed to recede somewhat at night. On January 16 she began to have cramp-like pains in the muscles of her legs, severe enough to cause her to flex her legs. Extension of the legs was very painful. Her temperature at this time was 102.2° F, pulse 128 and regular. No signs of meningitis were present. A blood count showed an eosinophilia of 31 per cent. A diagnosis of trichiniasis was made. On January 21 calcium gluconate with haliver oil and viosterol was started. The apparent effect of this therapy on the fever encourages us to believe that it may have brought about a shortening of the encystment stage.

CONTROL TESTS

The Bachman skin test was given to a series of patients in St. Francis Hospital who were admitted because of some other disease and who presented no obvious symptoms of trichiniasis. Table 2 shows the results of these control tests. All of the tests were entirely negative except one (L L) which was as strongly positive as any of those obtained in the cases tested in Sections I and II. This patient (L L) gave a history of having eaten raw sausage sandwiches over a period of years and gave a vague history of muscle pains which were believed to be arthritic. She remembered no edema. Her blood count at the time of the test showed 4 per cent of eosinophiles. In view of these findings and her history we regard this as an unrecognized case of trichiniasis discovered by the Bachman test.

COMMENT ON SKIN TESTS

The results from the use of the Bachman test have been quite favorable when used and read correctly. Goldschlager⁵ reports a series of eight cases

all positive to the test. All of his controls were negative except one which he attributes to a phenol sensitivity. Drake,⁶ in a series of 24 cases in which the tests were satisfactorily applied, reports all positive or 100 per cent. In 25 cases that had eaten the infested meat and gave no history of illness but had eosinophilia, only 12 reacted positively to the test, about 50 per cent. McCoy⁹ selected 88 patients that had had the infestation within the past eight years. Of 36 of these who had been ill two to six weeks, 31, or 92 per cent, gave a positive test. Of 39 tested from three to 22 months after infestation, 31 or 80 per cent were found to be positive. Of 13 persons ill three and a half to seven and a half years prior to the test, a total of eight or 62 per cent were positive. He also adds that in 539 tests only seven persons were found to be sensitive to the control injection. Summarizing the above experience (and excluding all cases of McCoy's tested more than six weeks following infestation) the tests were positive in about 95 per cent of the cases.

Our experience with the Bachman test has been very satisfactory. We believe it is as efficient as the average diagnostic skin tests in other fields. We obtained positive reactions in every one of our small series of cases (table 1). The accuracy of the test depends upon securing a suitable preparation of powdered larvae and properly preparing the antigen solution from the powder. At present there is no adequate supply of the material available. New antigen must be prepared frequently. If kept on ice, it is reported to retain its potency for about six months. If not kept on ice it deteriorates much more rapidly. We found one such preparation inert after two months. We believe the commercial production and distribution of powdered trichinella larvae for antigen would be a definite service to the profession.

We did not utilize the Bachman precipitin test⁸ in this study. This test usually does not become positive until three or four weeks after infection. However, it would aid in detecting border-line cases which are of greater duration than this. Bachman,¹⁰ in a report of his work in Puerto Rico, showed that this precipitin test is 90 per cent specific.

CONCLUSIONS

1 Eight cases of trichiniasis with recovery are reported which were all positive to the Bachman intradermal skin test.

2 A résumé of the incidence of the disease in Ohio shows 96 cases in the last eight years with a mortality of 8.33 per cent.

3 The Bachman intradermal skin test is a valuable diagnostic aid in trichiniasis and should supplant the biopsy of muscle.

CHRONIC ULCERATIVE COLITIS FACTORS INFLUENCING ITS RESPONSE TO SPECIFIC TREATMENT *

By WYATT C SIMPSON, M D , and J ARNOLD BARGEN, M D , F A C P ,
Rochester, Minnesota

KNOWLEDGE of the condition that is known as "chronic ulcerative colitis" seems to date at least to the "bloody flux" of Sydenham, in 1669

Its bacterial etiology has been recognized only recently. Etiologic significance has generally been ascribed to the diplostreptococcus originally described by one of us

The similarity of this disease, because of its destructive character, to tuberculosis has frequently been emphasized. This fact has made it difficult to evaluate any single therapeutic agent employed in its treatment. Even though many clinicians seem to recognize its similarity to tuberculosis they frequently have not comprehended the importance of a therapeutic regimen similar to that generally accepted for tuberculosis. A carefully regulated and properly organized program of management for this disease cannot be overemphasized. It was with this thought in mind that the study recorded here was undertaken. We have tried to evaluate the part played in this program by our serum therapy or specific therapy.

Two of the major efforts in the treatment of this disease have been to immunize victims of this disease against the diplostreptococcus of colitis and to remove sources distant from the colon that might harbor this organism. Results of cultures of the rectal discharges of these patients have been recorded. An attempt has been made to correlate the incidence of positive culture and the immediate result of treatment.

We have reviewed the cases of chronic ulcerative colitis in which treatment was given during a given period of time to see whether response to treatment varied in the cases in which the diplostreptococcus was found and in those in which the culture of the rectal discharges was reported as negative. Table 1 will illustrate the degree of immediate improvement following our program of management, which included as one of its major efforts the administration of the serum. It will be noted that the patients failed to respond to treatment in only 11 per cent of the cases. These were all cases in which all objective tests lead to the diagnosis of chronic ulcerative colitis or colitis gravis, the type in which the diplostreptococcus is usually found. Grade 1 improvement refers to the group in which there was a slight but unsustained improvement. Grade 2 refers to moderate but continuous improvement, and grade 3 refers to marked improvement with relief of all symptoms and no exacerbation of symptoms up to the time of this review. Grade 4 refers to complete and prompt relief of all symptoms. The latter

* Submitted for publication January 13, 1937

TABLE I

Degree of Improvement in 181 Cases of Chronic Ulcerative Colitis

Culture for Diplo- streptococcus of Colitis	Grade of Immediate Improvement Following Treatment										Total
	0		1		2		3		4		
	Cases		Cases		Cases		Cases		Cases		
	Num- ber	Per Cent	Num- ber	Per Cent	Num- ber	Per Cent	Num- ber	Per Cent	Num- ber	Per Cent	
Positive	7	8	9	10	38	43	20	23	14	16	88
Negative	14	15	16	17	35	37	18	20	10	11	93
Total	21	11	25	14	73	40	38	21	24	13	181

group can truly be called healed. A review of this table will promptly suggest that there is no material difference in the response of patients with "positive" cultures and those with "negative" cultures. One might be inclined to infer from this that the improvement which follows treatment is unrelated to the presence of the diplostreptococcus. However, a review of table 2 will promptly dispel such an inference. It will be seen how difficult it is to call a culture "negative" until repeated cultures have been attempted.

TABLE II

Number of Cultures Attempted in 259 Cases before a Positive Culture Was Obtained or a Negative Culture Was Declared

Results of culture	Number of cultures						Number of cultures not analyzed	Total
	1	2	3	4	5	5+		
Positive	86	12	5	2	2	1	35	143
Negative	44	25	19	11	5	12		116

Table 2 presents a review of the number of attempts to culture the rectal discharges of each patient. The number of patients studied in the two series do not correspond in all details because, as would seem obvious, not all patients who have any type of disease can be accurately controlled. The 259 patients represent those who were observed for more than a year.

Table 3 illustrates the amount of bowel involved in a group of 172 cases. The extent of involvement has been graded 1, 2, 3, and 4, corresponding roughly to the four segments of the bowel, that is, involvement, grade 1,

signifies that the process is confined to approximately a fourth of the length of the large bowel. In these cases the involvement was predominantly in the rectum and sigmoid colon, but in a few instances it was only in the cecum and ascending colon or only in the descending or transverse colon. Grade 4 involvement signifies involvement of the entire colon, no special designation being given to those cases (18 in this series) in which roentgenologic examination revealed that there also was involvement of the terminal portion of the ileum.

TABLE III
Relation of Extent of Involvement to Grade of Improvement

Extent of involvement	Grade of improvement										Total	
	0		1		2		3		4			
	Cases		Cases		Cases		Cases		Cases			
	Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent
1	2	4.7	3	7	16	38	15	35	7	16	42	24.4
2	3	19	3	19	4	25	5	31	1	6	16	9
3	1	10	2	20	7	70	0	0	0	0	10	5.8
4	13	12.5	15	14.4	45	43.2	19	18.3	13	12.5	104	60.4
Total	19	11	23	13.4	82	46.5	39	22.7	21	12.2	172	

Study of table 3 reveals that the preponderant percentage of cases (60.4 per cent) falls into the group in which the involvement was grade 4, the others follow in the order 1, 2, and 3. Furthermore, it will be seen that no important relationship can be drawn between extent of involvement and degree of improvement. Patients whose entire colon was involved seemed to respond equally as well to treatment as did those who had involvement of only one segment.

Further study of these cases will reveal that, while the amount of bowel involved has no material relation to the response to treatment, the activity of the disease and the length of time a patient has been ill are definite factors which affect the response to treatment. Even though there is involvement of the entire large intestine, if the degree of activity of the disease is mild, the response to treatment is quicker and more actively sustained, the relief of symptoms is more likely to be complete than if the bowel is involved by more active disease. Obviously, when the disease has lasted for months or years, its continuous onslaught on the bowel will produce damage which may be irreparable. That the length of time the patient has had the disease bears

some relation to the response to treatment is illustrated by table 4. This table would suggest that the benefits to be expected from treatment of chronic ulcerative colitis bear an inverse ratio to the duration of the disease. No one can say just how large a part the administration of serum plays in the therapeutic response in these cases. The fact that relief is frequently dramatic, improvement is rapid, and progressive and complete restoration to normal occurs, suggests that the administration of serum plays a part in the improvement. The fact that improvement is usually slow, even though progressive, would suggest the importance of all the other accessory therapeutic endeavors.

TABLE IV

Relation of Grade of Improvement and the Duration of Symptoms before Treatment

Duration	Grade of Improvement										Total
	0		1		2		3		4		
	Cases		Cases		Cases		Cases		Cases		
	Num- ber	Per Cent	Num- ber	Per Cent	Num- ber	Per Cent	Num- ber	Per Cent	Num- ber	Per Cent	
1 year or less	7	11	6	10	20	32	12	19	17	27	62
1 to 5 years	8	10	9	12	37	48	19	25	3	4	76
5 years or more	6	14	9	21	16	38	7	16	4	10	42
Total	21		24		73		38		24		180

This review would further substantiate the opinion previously expressed that surgical interference in these cases should be confined to complications of the disease for many of the patients, even though they make but little immediate response, will in the course of months improve and finally the disease will be completely arrested as far as any intestinal symptoms are concerned.

Another interesting point concerning intestinal disorders was observed during the time that this series of cases of chronic ulcerative colitis was studied. In cases of diarrhea the patients were sent to the laboratory for culture of the stools. Table 5 illustrates the number of these cases in which the diplostreptococcus was found, but in which there was no objective evidence of chronic ulcerative colitis. These cases represent only a very small fraction of the cases of diarrhea in which cultures for this organism were made during the period of this study. Several of the patients in these cases passed blood later during an attack of acute pharyngitis. Others who had an irritable colon improved as a result of the administration of anticolitis

vaccine Others experienced an attack of diarrhea following the administration of too large a dose of the vaccine These observations would suggest a subclinical condition of colitis and would suggest the nature of treatment advisable in selected cases of this type

TABLE V

Cases in Which the *Diplostreptococcus* Was Present without Objective Evidence of Chronic Ulcerative Colitis

Final Diagnosis	Cases
Irritable colon	16
Deficiency diarrhea	3
Subacute purulent appendicitis	1
Typhoid fever	1
Amebic dysentery	1
Diverticulosis	1
Tuberculous enteritis	1
Rectal abscess	1
Chronic infectious arthritis	1
Simple diarrhea	1

SUMMARY

The importance of a well-ordered program of treatment in cases of chronic ulcerative colitis cannot be overemphasized When all objective tests point to a diagnosis of chronic ulcerative colitis, even though positive cultures for the *diplostreptococcus* are not obtained, specific treatment should be given The number of attempts which should be made to culture rectal discharges and to culture the lesions directly through the proctoscope remains unsettled In many cases in which the culture is reported "negative" on first culture, the culture will become "positive" on repeated cultures This fact emphasizes the difficulties of making cultures of the stools and the importance of following details of a well-ordered technic

Response to treatment varies inversely with duration of the disease and directly with its activity and severity Patients who harbor the *diplostreptococcus* of colitis and who have diarrhea, even though they have no proctoscopic evidence of the disease, may be saved much trouble by undergoing treatment for subclinical types of colitis

FURTHER OBSERVATIONS ON RAPID HYPOSENSITIZATION¹

By G L WALDBOTT, M D, F A C P, and M S ASCHER, M D,
Detroit, Michigan

RECENT textbooks on allergy make only little mention of rapid hyposensitization[†] treatment and only a few clinicians have given this method serious consideration. The method of administering small increasing doses of antigen at short intervals was first introduced by Besredka¹ for the avoidance of serum reactions after he had observed that in animals the re-injection of a sublethal dose of antigen resulted in a temporary state of anti-anaphylaxis and that during this state larger doses of antigen could be more readily tolerated.

In 1930 Freeman² adopted this method of treatment for the relief of patients with hay-fever and asthma. His case reports, however, rather tend to discourage its application for clinical use. He was forced to add epinephrine to each injection because of the occurrence of severe constitutional reactions, yet, in spite of this precaution such reactions occurred. Tuft³ and Blankenhorn³ reported cases of shock and death following injections of horse serum in patients in whom desensitization had been attempted by giving increasing doses at short intervals.

For some time past, we have attempted to adapt this method to clinical application in allergic patients suffering from asthma and hay-fever. At first we met with little success because of the frequency of severe reactions. In a preliminary report⁴ we concluded that this procedure was not devoid of danger. Our interest was greatly stimulated after we had begun to use co-seasonal treatment for hay-fever and asthma. This mode of treatment taught us two principles which we found to be the key to any form of hyposensitization, namely, to start with a sufficiently small dose and to gauge the dose of subsequent injections from the size of the local wheal obtained on the site of the previous one.

INDICATIONS

With co-seasonal treatment, we found as have Vaughan,⁵ Phillips⁵ and others that prompt relief from hay-fever can be established in many instances. The beneficial results, however, are often transient and in the severe cases inadequate (especially is this true in pollen asthma). If more lasting results are to be obtained it is essential to reach a higher final dose.

* Received for publication January 25, 1937.

† The term "hyposensitization" is used by some in order to indicate that "complete" desensitization, as in an anaphylactic animal, is impossible in man. We do not believe that such a distinction is possible since in man no one has ever given, for the purpose of desensitization, doses corresponding even approximately to those given to an anaphylactic animal per kilogram of body weight. However, we shall adhere to the common nomenclature to avoid confusion.

Recent experience has convinced us that in severe chronic asthma in which the causative antigens are known this is the method of choice. Another main indication for this treatment exists in patients with hay-fever or asthma in whom the time for treatment is limited. It has also proved successful in cases of atopic eczema of known etiology. In cases of marked multiple sensitivity in which the diet was greatly restricted, it has been of great value to us in the effort to counteract sensitization to those antigens which were most important in keeping up the patient's nutritional state. We are particularly referring to rapid hyposensitization against such foods as milk, wheat and egg. Although we have only a limited experience with the prevention of "allergic" shock following therapeutic or prophylactic injections of animal serum, we believe that the principles advocated here are applicable to any form of serum therapy.

TECHNIC

Our technic is as follows. The initial dose should be such that the resulting wheal from the injection will have subsided within 45 minutes. This can be accomplished if we use, for example, a dose as low as $\frac{1}{2}$ Noon unit (0.0005 mg.) of pollen extract, in an average pollen case. In the more sensitive individuals this dose is reduced, in the less sensitive ones as high as 3 units (0.003 mg.) to 5 units (0.005 mg.) are given as the initial dose. This infers, of course, that the patient has actually been found to be sensitive to the specific antigen and that a larger dose will produce the usual local reaction. As a guide we routinely perform scratch tests at first. Should they be markedly positive (as in case 2, in which a scratch test with ragweed extract produced a generalized reaction), we repeat the tests after an interval of 15 to 20 minutes in order to establish local wheals repeatedly. After having thus produced moderate sized wheals one can more easily build up the first intradermal doses. As antigens we employed mostly pollen but also any of the other inhalants, foods, and other substances which we felt, by skin tests and clinical evidence, were of primary importance. We frequently used combinations of various antigens. No different therapeutic response was noted whether the injection was given intradermally or subcutaneously. The intradermal injections, however, because of the more distinct appearance of the wheal, were of greater service as a gauge for further treatment.

If the preliminary injections result in no, or little local whealing the subsequent ones may be given at very short intervals (10 to 15 minutes) and the increase may be from 50 to 200 per cent of the previous dose. After the desired wheal is obtained, the injections must be increased more slowly (from 10 to 30 per cent of the previous dose) and the intervals made longer (from 2 to 6 hours). If no swelling is obtained upon the rapid increase of doses and frequent injections the case should be re-investigated and search for other antigens be made.

If too large a swelling occurs or if an aggravation of the existing symptoms takes place, the treatment should be discontinued for 6 to 8 hours and then renewed with lower doses

REACTIONS

Marked local edema at the site of injection may be indicative not only of an early reaction, if it appears rapidly, but also of a delayed "allergic" reaction. This may occur six to ten hours after the treatment had been administered. If an early constitutional reaction is encountered, we give no, or very little epinephrine ($\frac{1}{20}$ to $\frac{1}{10}$ c c) as the use of epinephrine may mislead us in gauging the doses for the subsequent treatment. This is in contrast to the technic advocated by Freeman who administered epinephrine frequently together with the antigenic extract. After a generalized reaction has occurred we discontinue the injections for a given period and decrease the subsequent doses. In such a case it is sometimes desirable to stop the treatment for a whole day and to continue with smaller doses without a subsequent immediate increase.

In "intravenous" or "backseepage" reactions (Waldbott and Ascher⁶) which are evidenced by their immediate onset (within 10 seconds to a few minutes) and occasionally by bleeding upon the site of injection, epinephrine is, of course, indicated in large doses.

As a rule we do not set ourselves a definite goal as to the final dose. In the effort to reach too high a dose one may produce constitutional reactions and thus defeat the purpose of the treatment, namely, immediate improvement. We do, however, often reach a final dose as high as is customary in hyposensitization treatment.

RESULTS

In discussing the results obtained, two questions should be dealt with separately. Firstly, is it possible to reach safely large doses in a relatively short period of time? Secondly, how does the improvement resulting from this treatment compare with that attained by other methods? Chart 1 presents data bearing on the first point from a group of seven consecutive cases and indicates that within a period of four to seven days, doses as high as 8000 units of pollen extract can be reached without untoward effect. It should be emphasized that all the cases included here were found definitely sensitive to the antigens administered. Even in cases in which constitutional reactions occurred relatively large doses could be reached as seen in chart 2.

In comparing end results with those obtained by other methods the question of proper controls is very complicated. Practically anything may "cure" an asthmatic at any time. Especially in the chronic asthmatic such measures as hospitalization, discontinuance of epinephrine or other drugs and such natural means of relief as the termination of a pollen season, of

a fungi season, of an infection, etc., may contribute to or induce a "cure" Furthermore, a patient apparently "cured" for a considerable period of time may at any time under certain circumstances have a flare-up of the previous disease merely because of an unusually heavy exposure to antigens to which a latent sensitivity may exist That previously positive skin reac-

Chart 1 demonstrates how relatively high doses of extract can be reached in a short time in seven consecutive pollen cases

tions become negative after administration of antigen at 'short intervals was recently shown by Rackemann and Wagner' This, however, again cannot be considered a criterion of a "cure" To speak of a "percentage of cure," as it is often done, particularly in connection with hay-fever therapy, is again subject to the above objections

Chart 2 demonstrates the increase in doses following constitutional reactions in four selected pollen cases

Conforming with the purpose and the indications of this method of treatment and the difficulties involved in establishing adequate methods of control, we therefore do not concern ourselves with the late effects of this treatment, but are merely recording the clinical improvement, i e, the relief of symptoms noticeable during a period of several weeks. In the pollen cases of this series this period of time extended throughout the respective pollen season. All our patients were instructed to return to the office or to notify us immediately upon the return of any symptoms at any time. A recent follow-up on the cases included here, assured us that this instruction had been carried out and reaffirmed our previous opinion.

The treatment had been administered to more than 300 patients. Of these we selected 146 in whom we felt that as adequate a control as possible had been established. We are referring here to the discontinuance of other therapeutic measures, to the lack of success with such measures, to the length of time during which the patients had been under our observation before and after the treatment, as well as to the general trend of allergic symptoms as influenced by the climatic condition of the respective season. In these patients we, furthermore, had evidence to believe that the antigens used were the primary causative agents.

Among these 146 cases, there were 78 with hay-fever, 61 with asthma, or asthma combined with hay-fever, 7 with atopic eczema. Fifty-two became entirely free from symptoms, the improvement becoming noticeable immediately after the first few injections. 83 patients were considerably improved, 11 failed to respond to the treatment. Among the 83 patients who were "considerably improved," 21 had what we considered to be late reactions, which were evidenced by a temporary aggravation and which were followed by subsequent freedom from symptoms. With our advancing experience the number of these reactions has been reduced. Most of the asthmatics had been in a rather severe asthmatic state. Thirty-nine out of the 61 had to be hospitalized. Of these 39, only four failed to show definite improvement.

The following are the protocols of three representative cases.

CASE REPORTS

Case 1 Mrs F B, aged 46, was admitted to Grace Hospital on June 4, 1936 at the height of the grass pollen season with a severe attack of bronchial asthma. She had been treated by such measures as epinephrine, $\frac{1}{8}$ to 1 c c, eight times a day, opiates, barbiturates, inhalation of stramonium powders, iodides by mouth and intravenously, and, at intervals of two to three days, injections with various antigenic substances to which she had shown positive reactions. In spite of this therapy the asthmatic state persisted. On the tenth day of admission all medication was discontinued. As no improvement took place during the two following days, 1 Noon Unit (0.001 mg) of a combination of grass pollens (Orchard Grass, June Grass, Red Top, and Timothy) was given intradermally, after preliminary scratch testing had shown two to four plus reactions to these pollens. Subsequent injections with a moderate increase were given at three hourly intervals so that a dose as large as 4500 units (4.5

mg) was reached on the fourth day After the third injection there was a definite subsidence of the asthmatic symptoms She was discharged from the hospital on the eighteenth day and remained under our observation for two more months, free from asthma

Comment This patient represents a typical instance in which hospitalization and other methods failed Here a rather high dose of antigen was reached within a short time, giving prompt and lasting relief

Case 2 Miss I D, aged 35, was seen in a severe asthmatic state on September 2, 1933, having had perennial allergic asthma for 18 years The patient had previously shown a marked sensitivity to the common pollens, epidermals and to a large number of foods On checking the dermal tests a marked generalized reaction was encountered within one minute after the application of a drop of concentrated extract of short ragweed upon the scarified skin According to the patient's statement a similar experience had occurred previously when she was given an injection of $\frac{1}{10}$ Noon unit (0.0001 mg) of ragweed pollen intradermally Being aware of this sensitivity we endeavored to produce frequent local wheals without injections, namely, by applying a drop of ragweed extract for a graduated period of time upon the scarified skin and washing it off at first after one second, then three seconds, then eight seconds, etc., at intervals of from one-half to two hours judging the time interval from the size of the local wheal produced At the end of the second day the patient could tolerate the extract on the scarified skin for 20 minutes without producing a generalized reaction A marked local edema had ensued after each application On the third day it was possible to inject a dose of $\frac{1}{50}$ unit (0.00002 mg) ragweed pollen, this was followed up at intervals of two hours by $\frac{1}{33}$ unit (0.00003 mg), $\frac{1}{20}$ unit (0.00005 mg), $\frac{1}{100}$ unit (0.00008 mg) On the sixth day 150 units (15 mg) was reached Upon the second application of the extract to the skin the asthmatic condition distinctly improved Soon after the first intradermal injection the patient became free from asthma with the exception of slight attacks at night, which subsided entirely after two more days, in spite of the fact that the ragweed pollen season had not yet been terminated

Comment In this case an unusually marked degree of sensitivity was combated by rapid hyposensitization treatment The production of local wheals either by scratch or subcutaneous application of the antigen must have been instrumental in bringing about prompt relief While unquestionably various other antigens were contributing to this patient's asthmatic condition, the control of what appeared to be the principal reactor at that time, we believe, aborted the attack

Case 3 Miss T F, 52 years old, had had severe attacks of asthma during the past 10 years lasting as a rule from late May to the middle of October Two sisters had also been suffering from allergic asthma On skin testing positive reactions to the grass pollens, the ragweeds, orris root, wheat and egg were obtained Admitted to the Charles Goodwin Jennings Hospital on August 11, 1936, with severe asthma, she was treated with a combination of antigenic extracts 1 to 4 units (0.001 to 0.004 mg) of pollen in conjunction with epinephrine, ephedrine, barbiturates The condition became progressively worse In addition to 4 to 6 daily doses of epinephrine, opiates, calcium, iodides, oxygen and glucose intravenously were resorted to On the fourth day of admission when the patient was seen by one of us (G L W) all medication was discontinued except for $\frac{1}{10}$ or $\frac{1}{20}$ c c, of 1:1000 epinephrine given

about two to four times in 24 hours. This resulted in no change of the severe asthmatic state. The following morning the patient was placed on a rapid hyposensitization regime starting with an initial dose of $\frac{1}{10}$ unit (0.0001 mg) of pollen extract with a very slight increase of doses at hourly intervals. The first five injections did not cause local swelling. When a slight wheal was obtained with the sixth dose, 2 units (0.002 mg), a decided improvement was noted. However, the asthma did not completely subside. For the following injections another extract was employed with which no more wheals were obtained in spite of a rather marked increase in doses (It was determined later that this extract had not been made up in the usual manner and was of very little potency). The asthma recurred and became gradually worse until the patient again was in a critical condition. An intramuscular injection of 50 c.c. of serum from a patient recovered from pollen asthma was of no avail. Assuming that the lack of response to the treatment might be due to the insufficient potency of the extract it was replaced, without the patient's knowledge, by the one previously used. The initial dose $\frac{1}{10}$ of 1 unit (0.0001 mg) produced a wheal of about $2\frac{1}{2}$ cm in diameter with pseudopods. Relief was noted after 20 minutes. Subsequent treatments were given at intervals of one to three hours. Although the doses were increased only very slightly, local reactions occurred after each injection. On August 23 a dose of 80 units (0.8 mg) was reached. The patient was discharged from the hospital a few days afterwards.

Comment This represents another patient with severe asthma in a critical state in whom various therapeutic measures had failed. Here again, the improvement coincided with the production of local reactions by the antigen. The failure to elicit such reactions apparently resulted in a relapse. An impotent extract accounted for this fact. It is noteworthy that the dose of 0.1 unit failed at first to elicit a local reaction while after four days, it resulted in definite wheals.

CONCLUSIONS

1 Rapid hyposensitization, we believe, deserves a definite place in the treatment of allergic diseases. Particularly in the severe asthmatic in whom the causative antigens are known, it has proved to us to be the method of choice.

2 Successful treatment by this method is dependent on the administration of the proper antigen or combination of antigens, i.e., those which form the patient's dominant sensitivity.

3 The danger of causing constitutional reactions or of aggravating existing symptoms can be obviated if one abides by the following principles:

a The initial dose should be sufficiently low so as not to produce much local swelling.

b The doses and intervals between treatments should be carefully gauged for each individual injection, the principal guide being the degree of local edema which is produced by the previous one.

c An incipient constitutional reaction which may merely manifest itself by a temporary aggravation of existing symptoms should be recognized and carefully guarded against by a readjustment of the proposed schedule of treatment.

d No epinephrine, or as little as possible, should be used in conjunction with the treatment in order not to interfere with the production of a local swelling

THE THERAPEUTIC USE OF VENESECTION IN POLYCYTHEMIA

By D J STEPHENS, M D , and NOLAN L KALTREIDER, M D ,
Rochester, New York

ALTHOUGH venesection has been used for many years as an emergency measure in erythremia, its general use as a therapeutic agent in this disease has been considered contraindicated on the grounds that reduction of the blood level by this means would act as a further stimulus to erythrocyte production¹ Recent investigations, however, have indicated that this assumption may be unwarranted Falconer² has shown that the repeated removal of from 200 to 600 c c of blood at intervals of from a few days to three weeks did not increase the reticulocyte percentage above normal limits Reimann and Breuer³ have studied the effects of systematic venesection in seven patients with polycythemia vera Reduction in the red blood cell and hemoglobin level was accomplished by repeated bleeding over a period of several weeks The resulting symptomatic and hematologic remissions were maintained for an average period of two years without further treatment Detailed studies of the effect of venesection on the various other hematologic and circulatory abnormalities characteristically found in polycythemia have not been encountered in the literature

This communication reports the results of a study of the therapeutic effect of venesection in the treatment of five cases of erythremia in whom the use of phenylhydrazine was considered inadvisable because of age or a history of previous vascular thrombosis⁴ In addition to clinical observations and determination of the red blood cell and hemoglobin levels and the reticulocyte percentage, studies of the hematocrit, blood volume, blood viscosity and, in some instances, circulation time and oxygen saturation of the arterial blood were made before, during and after periods of bleeding Two (R R and A G) of the five patients studied presented the characteristic picture of polycythemia vera, without demonstrable cause for the high hemoglobin and red blood cell levels Patients M M and M P have also been considered instances of polycythemia vera, although cardiac lesions, which may have led to some degree of anoxemia, were demonstrable, both exhibited splenomegaly and increased blood volume, usually not observed in the "secondary" types of polycythemia The polycythemia of patient S W was apparently secondary to pulmonary fibrosis

METHODS

Venesection was accomplished either by the multiple syringe method or by the withdrawal of blood through a large needle into a flask under negative

* Received for publication January 28, 1937

From the University of Rochester School of Medicine and Dentistry and the Medical Clinics of the Strong Memorial and Rochester Municipal Hospitals, Rochester, New York

pressure induced by suction. As a rule, 500 cc of blood were withdrawn at intervals of from one to three days until the desired red blood cell, hemoglobin or hematocrit level was reached. In general, an attempt was made to reduce the hematocrit to a normal or slightly subnormal value. Red blood cell and white blood cell counts were estimated with the use of pipettes and counting chambers certified by the U S Bureau of Standards. For each red blood cell determination the average of two counts made in the usual manner was taken. Hemoglobin values were estimated in the Sahli hemoglobinometer, frequently calibrated by oxygen capacity. Reticulocyte counts

S.W. # 47306

FIG 1

were made in "wet" preparations, stained with cresyl blue, 1,000 cells were counted for each determination. The relative volume of the red blood cells was determined by the Wintrobe hematocrit method⁵. Blood viscosity was determined by means of the Hess viscosimeter at 100m temperature. Blood velocity was determined as the arm to tongue circulation time by the Decholin method*. The blood volume was estimated by the method of Keith, Rowntree and Geraghty,⁶ as modified by Hooper, Smith, Belt and Whipple⁷. We have some doubt as to whether the values obtained for blood volume in the presence of a high hematocrit value represent a close approximation of the actual volume of circulating blood when determined by this method. There

* The decholin-sodium used in these experiments was generously supplied by the Riedel de Haen, Inc

is reason to believe that complete mixing of the dye may not occur in the time interval allowed to elapse between the injection of the dye and removal of the sample for determination of the dye content of the plasma, because of the marked increase of the blood viscosity and slowing of blood flow. The values obtained are probably lower than the actual blood volume. Although there may be some doubt as to the reliability of the absolute values

FIG 2

obtained in the presence of a high hematocrit and increased blood viscosity, a comparison of the effect of therapy on the blood volume estimations is of interest and some significance

The following case reports are supplemented by summaries of hematologic observations presented in figures 1 to 4 and table 1. Some of the earlier observations in case 1 were made by Drs S H Bassett and A Hurtado in connection with studies of the iron balance

CASE REPORTS

Case 1 S W, a 56 year old foundry worker, was admitted to the hospital on May 12, 1931 complaining of shortness of breath, "purplish color of the skin" and smothering sensation under the sternum of one year's duration. About six weeks before admission these symptoms became more intense. On admission the patient was orthopneic, and the respirations and pulse were rapid. The mucous membranes and nail beds were deeply cyanosed. The retinal veins were engorged and the neck veins greatly distended. Moderately coarse râles were scattered throughout the entire chest. The heart was markedly enlarged to the left. The liver was enlarged, but the spleen was not felt. There was pitting edema over the lower extremities.

The blood findings were as follows: red blood cells 7,300,000 per cu mm, hemoglobin 19.5 grams per 100 c.c., hematocrit 67.7 per cent and white blood cells 11,600 per cu mm. The electrocardiograph showed right axis deviation. Roentgenogram of the chest revealed the heart to be greatly increased in all of its diameters. The pulmonary fields showed diffuse, fine reticular fibrosis, in addition to soft mottling and feathering over the lower fields. The vital capacity was 650 c.c.

The patient was treated by venesection (1,000 c.c.) and oxygen inhalation and on discharge one month later was much improved.

The patient was next seen in September 1931 and April 1932, at which time he was again dyspneic and orthopneic at rest. The pertinent findings in reference to the blood are shown in figure 1. With the removal of a total of 2,100 c.c. of blood, the red blood cell count, hemoglobin, hematocrit, blood volume and viscosity fell to slightly below the average values for normal individuals. There was no appreciable increase in the reticulocyte percentage. The oxygen saturation of the arterial blood rose from 67 to 87 per cent. When the patient was discharged from the hospital on June 27, 1932, his cardiac compensation was good for moderate activity and dyspnea was considerably ameliorated.

Twelve months later, the patient was again seen because of recent increase in dyspnea. The blood findings are given in figure 1 and show that there was again a marked increase in the red blood cell and hemoglobin level. After a series of venesections the level was again reduced to the normal zone where it remained for approximately two years. It is significant that none of the periods of bleeding in this patient were followed by any increase in the reticulocytes.

Case 2 R R, a 40 year old brewmaster, was seen in this clinic in June 1934, because of a hematoma of the left thigh which had appeared following a fall. At this time the spleen was not felt and the red blood cell and hemoglobin levels were within normal limits.

In May 1935, the patient was readmitted to the hospital because of inability to talk and use the right arm and leg. For several weeks his wife had noted that the face and hands were becoming increasingly red and dusky. Examination revealed a red discoloration of the skin, particularly noticeable on the face, neck, hands and mucous membranes. The retinal veins were engorged and there was a small retinal hemorrhage lateral to the left disc. The spleen was palpable two fingers-breadth below the costal margin. Neurological examination showed right facial weakness and complete paralysis of the right arm and leg. Details of the examination of the blood are given in figure 2. In addition to these, the white blood cell count was 36,400 per cu mm and the icterus index, 32.

During a period of 5 days a total of 2,000 c.c. of blood was removed by venesection. Immediately after venesection the serum proteins were decreased to 4.4 grams per cent. This period of venesection was followed by an increase in the reticulocyte to 63 per cent.

Six weeks later, because of an increase in the blood counts (figure 2), an addi-

tional 1,200 c c of blood were removed This was followed by a maximum reticulocyte response of only 17 per cent

After the patient was discharged in July 1935, approximately 3,000 c c of blood were removed over a period of a year There has been partial improvement in the paralysis and dysarthria and he has remained free of further symptoms referable to polycythemia The spleen has not been palpable during the past year Blood studies obtained in October 1936 through the courtesy of the patient's physician, Dr C B F Gibbs, were as follows Red blood cells 6,130,000, hemoglobin 9.2 grams per 100 c c, hematocrit 31 per cent, reticulocytes 0.8 per cent, white blood cells 16,600, icterus index 8 and blood viscosity 3.6 From July 1935 to October 1936 the mean corpuscular volume fell from 76 to 51 cubic microns and the mean corpuscular hemoglobin from 24 to 15 micromicrograms

Case 3 M P, a 56 year old housewife, complained of dull aching pain in the left upper abdomen of two years' duration During the past several months she had noted progressive enlargement of a mass in the left upper abdomen In addition there had been dizziness and faintness occurring frequently during the past few months and sensations of burning of the feet There had been several recent epistaxes In childhood she had had rheumatic fever and since the age of 25, until the past two years, she had had seasonal hay fever and asthma, occurring in the autumn At the age of 50, she had experienced an episode of severe precordial pain, accompanied by prostration and collapse Since that time she had taken digitalis regularly

In February 1935 physical examination showed a dusky violaceous discoloration of the face, neck and hands The mucous membranes were deep red in color The retinal veins were engorged The heart was enlarged to the left and to the right, the pulmonary second sound was accentuated A loud, rough, systolic murmur was transmitted from the apical region to the axilla The spleen was markedly enlarged, extending downward to the iliac crest The liver edge was palpable three fingers-breadth below the costal margin

The blood findings are given in detail in figure 3 Other pertinent findings were White blood cells 14,100 per cu mm with a normal differential count, mean corpuscular volume 69 cubic microns, mean corpuscular hemoglobin 19 micromicrograms Electrocardiographic tracing showed right axis deviation Roentgenogram of the chest showed increased linear markings with fine feathering of both pulmonary fields The heart was enlarged in all of its diameters

Between February 15 and March 7 a total of 1,700 c c of blood was removed by venesection Reduction of the red blood cell count was followed by symptomatic improvement and a slight reduction in the mean corpuscular volume and hemoglobin and in the size of the spleen During and after the period of bleeding there was no significant change in the white blood cell count or the differential count

After discharge from the hospital digitalis was continued in maintenance dosage Up to the present time, 20 months after venesection, there has been no significant change in the blood picture and there have been no symptoms referable to polycythemia The spleen has remained at about the same size as when discharged from the hospital Following venesection, this patient has maintained a mild degree of hypochromic, microcytic anemia without symptoms and without evidence of hemolysis or of excess red blood cell regeneration

Case 4 A G, a 55 year old housewife, was first seen in this clinic in 1930 at which time a diagnosis of duodenal ulcer was made Examination of the blood showed no abnormalities at that time The red blood cell count was 5,500,000 per cu mm, hemoglobin 14.2 grams per 100 c c

The patient was admitted to the hospital in February 1935, complaining of frequent dizzy spells and increased color of the face and hands of several months' duration On examination deep red color of the face and hands was noted The retinal

veins were dilated. The heart and lungs were negative. The lower border of the spleen was felt five fingers-breadth below the costal margin. The liver edge was at the costal margin. The left foot and the lower left leg were cyanotic and swollen, apparently due to thrombosis of the deep veins of the leg.

Laboratory data in addition to those charted in figure 4 revealed an oxygen saturation of the arterial blood of 94 per cent, icterus index of 8, and a white blood cell count of 9,800 per cu mm with a normal differential count. Roentgenogram of the chest showed no pulmonary or cardiac abnormalities.

During a period of 14 days a total of 3,370 c.c. of blood was removed by repeated venesection. The maximum reticulocyte count during and after the period of bleeding was 12 per cent. At the time of discharge from the hospital the abdominal symptoms, the dizziness, faintness and the pain in the left foot had disappeared. The spleen decreased in size so that it was no longer palpable.

The patient was observed at intervals in the Out-Patient Department. The symptomatic and hematologic remission induced by venesection continued for approximately one year. In February 1936 occasional dizziness was experienced, during the next four months the frequency of the attacks increased and there was a gradual rise in the number of red blood cells. The spleen again became palpable two fingers-breadth below the costal margin. In June 1936 it was decided to observe the effect of a course of phenylhydrazine for comparison with the effect of venesection. During the period of hemolysis the reticulocytes increased to 48 per cent, mild jaundice appeared and was accompanied by an increase in the icterus index to 30. During the period of blood destruction the serum proteins increased from 6.3 to 7.2 grams per cent and the white blood cell count from 6,450 to 21,100 per cu mm with some increase in the percentage of neutrophils, no immature white or red blood cells appeared in the peripheral blood. The white blood cell count and differential count, the icterus index and the serum protein returned to pre-treatment levels within three weeks after discontinuance of the administration of the drug. The dizziness disappeared with the reduction in the blood level, but there was no significant change in the size of the spleen. Within two months the red blood cell count had risen to the pre-treatment level (figure 4) and symptoms had returned. A second course of treatment with this drug was given with similar results. In this patient the administration of phenylhydrazine was accompanied on both occasions by marked increase in ulcer symptoms, so that she refused to take a maintenance dose of the drug.

Case 5 M. M., a 40 year old stenographer, was admitted to the hospital in April 1933 complaining of fainting and dizzy spells of six years' duration. Her complexion had always been ruddy, but during recent years the bluish red color of her face, neck and hands had increased. There was a history of frequent epistaxes. In childhood she had had scarlet fever, chorea and poliomyelitis. At the age of 24 right salpingectomy and oophorectomy was done and at 27 she had peritonitis following an abortion. At 34 thyroidectomy was performed.

Physical examination showed bright, bluish red color of the face, neck, upper chest, hands and legs. There was slight exophthalmos and the retinal veins were engorged. The area of cardiac dullness was enlarged to the left, there was a pre-systolic thrill at the apical area, with systolic and presystolic murmurs. Blood pressure 160 systolic, 100 diastolic. The spleen was palpable three fingers-breadth below the left costal margin.

The hematologic picture is shown in table 1. The white blood cell count was 7,900 per cu mm. Differential count was as follows: neutrophils 58 per cent, lymphocytes 24 per cent, monocytes 5 per cent, eosinophiles 10 per cent and basophiles 3 per cent. Roentgenogram of the chest showed prominent linear pulmonary markings and cardiac enlargement. The electrocardiogram was normal.

During a period of 14 days, the patient received a total of 18 grams of phenyl-

hydrazine hydrochloride Two weeks later the blood level was slightly below normal (table 1) The viscosity of the blood fell from 15 to 6 and the blood volume from 91 c c to 72 c c per kilogram of body weight Following the administration of the drug the symptoms were ameliorated Within two months, in spite of the administration of small doses of the drug, the symptoms began to increase and the blood level began to rise

She was readmitted to the hospital in September 1933 because of a convulsive seizure The blood viscosity was 17 During a period of two months 2,000 c c of blood were removed by six venesections The maximum reticulocyte response during this period was 20 per cent

In February 1934 the red blood cell count was again elevated and phenylhydrazine (10 gram) was again given This course of the drug was followed by thrombosis of the left dorsalis pedis artery During the following 18 months the patient was followed at frequent intervals in the Out-Patient Department, receiving a total of 76 grams of phenylhydrazine in doses varying from 0.1 to 0.3 gram per week During this time there was progressive increase in the hemoglobin, hematocrit, viscosity and the mean corpuscular volume, although there was little change in the number of red blood cells (see table 1 under date 1/29/35) At this time the patient was having frequent fainting episodes and complained of tingling of the fingers In March 1935 after an epistaxis, which resulted in the loss of an estimated pint of blood, these symptoms became less severe

In April 1935 the removal of 1,500 c c of blood resulted in a hematologic remission of four months' duration It is of interest that on this occasion venesection was followed by an increase in the reticulocytes to 62 per cent In September 1935 the erythrocyte count had increased to such a level that 1,500 c c of blood were removed, again resulting in a decrease in the blood level to slightly less than normal (table 1) The maximum reticulocyte response following venesection on this occasion was only 20 per cent During the following eight months there was a slight rise in the red blood cell and hemoglobin values

In this patient there was only partial correlation between the blood level and the presence of fainting episodes, which were in many ways suggestive of petit mal seizures The changes in the size and hemoglobin content of the red blood cells following the use of venesection and phenylhydrazine were of particular interest and will be discussed

RESULTS

By means of repeated and systematic venesection at intervals of from one to several days it was possible to reduce the relative volume of the red blood cells to a normal or slightly subnormal level There was a corresponding decrease in red blood cells and hemoglobin and reduction in the blood viscosity, blood volume and blood velocity to approximately normal levels In two subjects, the oxygen saturation of the arterial blood was increased following venesection Hematologic improvement was usually accompanied by marked relief of symptoms referable to the polycythemia, and by reduction in the size of the spleen The characteristic "red" cyanosis disappeared and there were evidences of improvement in the capillary and venous circulation as the blood level was lowered The reticulocyte response to bleeding was of particular interest because of its significance as an index of erythropoietic activity Nine of the eleven periods of bleeding were followed by no significant increase in the percentage of reticulocytes It may

be of significance that the two periods of venesection which were followed by reticulocyte increases followed periods of blood destruction. In the case of patient M M the period of bleeding which was accompanied by a reticulocytosis of 62 per cent followed the prolonged administration of phenylhydrazine. Patient R R, when first seen, was jaundiced, with an icterus index of 32, interpreted as evidence of previous blood destruction. Four of the five patients experienced symptomatic and hematologic remissions of from eight months' to two years' duration without further treatment. Remissions of shorter duration were observed only in those patients who exhibited a reticulocyte response to venesection and who presumably had abundant stores of iron and other blood-building materials as the result of previous blood destruction.

Unfavorable reactions to venesection were not encountered, even when large amounts of blood were withdrawn within a period of a few days. No evidences of stimulation of the white blood cell or platelet elements of the bone marrow were observed. A temporary decrease in the level of the serum proteins was noted for a few days after the withdrawal of large amounts of blood but no clinical manifestations of serum protein deficiency appeared.

In one patient detailed observations of the effect of both venesection and phenylhydrazine are available (patient A G, figure 4). Satisfactory reduction in the red blood cells, hemoglobin, hematocrit and blood viscosity, and temporary relief of symptoms were accomplished by the administration of a relatively small dose of phenylhydrazine hydrochloride. In comparing the effect of the two therapeutic procedures in this patient, at least two significant and probably related observations are noteworthy. First, the administration of phenylhydrazine was followed by a reticulocytosis not observed after venesection. Second, the remission induced by phenylhydrazine was of less than two months' duration, as contrasted with a remission of 15 months' duration following venesection. As a result of the gastrointestinal symptoms which accompanied the administration of phenylhydrazine, this patient insists on returning to the use of venesection when further treatment of the polycythemia becomes necessary.

It is of interest that three of the five patients exhibited microcytosis and hypochromia of the red blood cells of significant grade. In two patients observations of the red blood cell size and hemoglobin content after treatment with both phenylhydrazine and venesection are available (table 1). In the case of patient A G, there was no significant change in the microcytosis and hypochromia during the 15 months' remission which followed venesection. The administration of phenylhydrazine, however, was followed within a relatively short period of time, by a consistent and significant increase in the cell size and hemoglobin content. Patient M M originally presented red blood cells which were normal in size and hemoglobin content. No significant change was observed after a single course of phenylhydrazine,

followed by a period of venesection. The administration of phenylhydrazine in maintenance doses during a period of one year, however, resulted in a significant increase in the mean corpuscular volume and hemoglobin. Although the number of red blood cells per cubic millimeter showed but little change during this period, the increase in erythrocyte size was sufficient to result in a gradual increase in the hematocrit, hemoglobin and blood viscosity, with coincident increase in the severity of symptoms. The removal of a total of 3,000 c.c. of blood by repeated venesection was followed by a significant reduction in the cell size and hemoglobin content.

DISCUSSION

The syndrome of erythremia is characterized by a marked hyperplasia of the bone marrow, as a result of which characteristic increases in the red blood cell count, hemoglobin, hematocrit, blood viscosity and blood volume occur. The symptoms of the disease result for the most part from the plethora and stasis of blood flow due to the marked increase in blood volume and the overfilling of the vascular tree, especially in the capillary bed. Splenomegaly is usually present. Phlebitis and vascular thromboses are common.

Although the primary lesion is in the bone marrow, there has been no unanimity of opinion as to the etiology of the pathologic increase in erythropoietic activity. There are those who have felt that the increased activity of the bone marrow is malignant in nature and analogous to the disordered cell activity which occurs in leukemia. Others have been impressed with the probable relationship of polycythemia to anoxemia, which is generally recognized as a powerful stimulant of erythropoietic activity. The "secondary" polycythemia observed in patients with cardiac and pulmonary lesions and the polycythemia encountered at high altitude would seem to be best explained on this basis. Further evidence of the probable importance of anoxemia has recently been provided by the studies of Reznikoff, Foot and Bethea.⁸ These authors observed distinct capillary thickening and subintimal and adventitial fibrosis of subarteriolar capillaries, arterioles and arteries of the bone marrow of seven patients with polycythemia vera. They raise the question whether the anoxemic state caused by vascular disease in the bone marrow itself may be responsible for the excess red blood cell production, particularly in those patients without obvious lesions in other viscera which might lead to anoxemia. With such an explanation of the bone marrow overactivity in so-called polycythemia vera, the erythremia and symptomatology of both types of polycythemia may be reasonably regarded as an overcompensatory response of the bone marrow to lowered oxygen tension. Even in those types of polycythemia in which the increase in red blood cells seems to be in response to an increased demand for oxygen-carrying material, the circulatory disturbances resulting from the increased blood viscosity and slowing of the blood flow may increase the difficulty in

oxygen exchange Under these circumstances the advantage gained by increase in hemoglobin may be more than offset by the disadvantage of circulatory embarrassment due to the increased corpuscular mass In such instances of "secondary" polycythemia, as well as in polycythemia vera, symptomatic improvement follows relief of the circulatory embarrassment by reduction in the number of erythrocytes by means of appropriate therapeutic measures

Of the various therapeutic procedures recommended for the treatment of erythremia, phenylhydrazine has been most extensively used and its effects most thoroughly studied Satisfactory hematologic and symptomatic remissions have been induced by means of this agent in a large number of reported cases Brown and Giffin⁹ have shown that reduction in the red blood cell count and hemoglobin is accompanied by reduction in the hematocrit, blood viscosity and blood volume and by improvement in circulatory efficiency Although the effect of a single course of phenylhydrazine is of relatively short duration, remissions may be prolonged by the continued administration of a suitable maintenance dose of the drug, the size of which must be individually determined A number of patients have been described in whom satisfactory remissions have been maintained for periods of many years¹⁰ Although the large majority of patients with polycythemia apparently may be satisfactorily controlled by the use of phenylhydrazine preparations, the use of this drug has certain practical as well as theoretical disadvantages The amount of the drug required to produce the desired effect varies widely from patient to patient Due to its cumulative and delayed action, the degree of hemolysis produced may be difficult to predict and control Instances of severe and even fatal anemia have been observed following its use in polycythemia Giffin and Conner⁴ state that it should be used with extreme caution, if at all, in elderly patients and in those in whom thromboses have been observed or suspected

The effect of phenylhydrazine on the blood and the bone marrow has been extensively studied in the experimental animal as well as in the patient with polycythemia Hemolysis is accompanied by the appearance of jaundice, increase in circulating bilirubin and increase in the urinary excretion of bile pigments and porphyrins Blood destruction induced by phenylhydrazine, however, results in no increase in the excretion of iron, which is retained and stored in the various organs, particularly the spleen and liver¹¹ It is apparent, therefore, that iron and perhaps other blood building materials, liberated by the hemolytic action of phenylhydrazine, are retained in the body for future use in erythropoiesis The use of the drug in polycythemia is usually followed by a marked leukocytosis, frequently with the appearance of immature myeloid elements in the peripheral blood Thrombocytosis also usually occurs and is thought to be responsible for the peripheral thromboses occasionally observed after the administration of phenylhydrazine Observations in humans, as well as in animals, have shown that phenylhydrazine, either directly or indirectly through its hemolytic action, is

a powerful bone marrow stimulant, resulting in proliferation of erythroid, myeloid and platelet elements of the bone marrow. The reduction in the red blood cell count is usually accompanied by reticulocytosis, leukocytosis and thrombocytosis, interpreted as evidence of increased bone marrow activity. The administration of phenylhydrazine to animals may be followed by the appearance of nucleated erythrocytes and immature myeloid cells in the spleen, liver and other organs.¹² Harrop¹ has suggested that intensive treatment with phenylhydrazine, radiation or venesection may be responsible for the leukemoid changes observed in some cases of polycythemia. It appears that, although phenylhydrazine, due to its hemolytic action, is capable of controlling the symptoms and peripheral blood picture of erythremia, its effect on the bone marrow may accentuate the existing marrow hyperplasia and may lead, through continued stimulation, to the appearance of leukemoid changes simulating myeloid leukemia.

Although there is a considerable literature dealing with the use of roentgen therapy in polycythemia, the effects of its use in this disease have not been extensively studied. Symptomatic improvement and reduction in the red blood cell and hemoglobin levels may follow irradiation of the spleen or long bones. Some students of the disease feel that roentgen therapy is the safest and most effective form of therapy available.¹

Recent reports have suggested the use of solution of potassium arsenite¹⁰ and repeated aspiration of the gastric contents¹³ in the treatment of polycythemia. The usefulness of these measures remains to be determined.

Objections to the general use of venesection in the treatment of polycythemia have been limited almost entirely to the assertion that it would result in increased stimulation of an already active bone marrow. This statement is apparently based primarily on observations of the results of hemorrhage in individuals with previously normal blood levels and on the result of bleeding experiments in animals. The degree of bone marrow stimulation observed under such conditions, however, appears to depend on several factors. Among these are the amount of blood lost, the resulting degree of anemia and the availability of iron and other blood building materials. The removal of as much as 500 c.c. of blood from a normal individual is followed by no reticulocyte response. However, the anemia occurring in humans after a large hemorrhage is followed by reticulocytosis and rapid regeneration of blood, provided adequate stores of iron and other blood building materials are available. It is significant that in those patients whose iron stores have been depleted by means of chronic blood loss, reticulocytosis and other evidences of blood regeneration do not appear until adequate amounts of iron are provided.¹⁴ Direct evidence that blood withdrawal results in increased bone marrow activity in erythremia is apparently limited to occasional observations of rapid red blood cell regeneration after reduction to anemic levels following a large hemorrhage. Our observations, as well as those of Falconer² and of Reimann and Breuer³ indicate that, in polycythemia, the use of venesection under controlled conditions is

not ordinarily accompanied by evidences of increased bone marrow activity. In this regard, it should be noted that only a slight, if any, degree of anemia is produced and that the withdrawal of the large amounts of blood necessary to reduce the hematocrit to a normal or slightly subnormal level results in the removal from the body of relatively large amounts of iron and other blood building materials. The prolonged remissions which follow reduction of the blood level by this means and the absence of reticulocyte response are interpreted as evidence that bleeding under these conditions may not result in significant increase in erythropoietic activity.

Venesection is a relatively simple procedure, the effects of which may be accurately controlled. Its use is apparently not attended by many of the dangers and undesirable side effects of phenylhydrazine and roentgen therapy. Its advantages and relative freedom of disadvantages would appear to warrant its more extensive use in the treatment of polycythemia, particularly, for the present at least, in those patients in whom the more orthodox therapeutic measures seem to be contraindicated or inadvisable.

A consideration of the erythrocyte characteristics in polycythemia, particularly in relation to the iron metabolism and the effect of therapeutic procedures is of interest. Hurtado¹⁵ noted that the polycythemia observed in natives living at high altitudes was characterized by a red blood cell which was larger, contained less hemoglobin and was less saturated with oxygen than the erythrocyte of normal subjects living at sea level. A marked increase in the hematocrit was observed, although the average number of grams of hemoglobin per 100 c.c. of blood had approximately the same value as the normal average at sea level. The corpuscular volume and the corpuscular hemoglobin varied inversely with the level of the red cell count, so that the hemoglobin concentration was found to be remarkably constant at approximately 25 per cent, considerably below the average normal of 34 per cent at sea level. These observations suggested that the adaptation processes to high altitude, from the point of view of blood morphology, were to be found not primarily in red cell and hemoglobin increases but rather in a close correlation between the cell number, volume and hemoglobin content and in the existence of a larger surface area in a given volume of blood and in the individual erythrocyte for the hemoglobin and oxygen content.

Similar studies of erythrocyte characteristics apparently have not been made in other types of polycythemia. It is usually stated that the size and diameter of the erythrocytes in polycythemia are normal,¹⁶ although the color index is nearly always decreased. In three of the five patients here reported, the mean corpuscular volume and hemoglobin content were well below the lower limits of normal and in one of these (R. R.) were further decreased after repeated venesection. In two instances (table 1) the cell size and hemoglobin content increased after the administration of phenylhydrazine, decreased following venesection. The microcytosis and hypochromia observed in these patients were similar to the changes which take

place in the erythrocytes in the iron deficiency anemias, suggesting that in at least some patients with polycythemia a relative iron deficiency may result from the increased demand for blood-building materials

A decrease in the average volume of the red blood cells in polycythemia should be physiologically advantageous, since the increased blood volume and blood viscosity, which are responsible for the stasis and slowing of blood flow, are due to the elevated hematocrit. The level of the latter is determined not only by the number of red blood cells per cu mm but also to a large extent by the mean corpuscular volume. Recent studies of the anemias¹⁶ have indicated that the size, volume and hemoglobin content of the erythrocytes are determined by the relative amounts of stroma and hemoglobin-building substances, particularly iron, which are available. If it may be assumed that, in the presence of adequate stroma-building material, the level of erythrocyte production in polycythemia is determined by the stimulating effect of anoxemia, then the size of the red blood cells delivered to the peripheral circulation should depend on the amount of iron available for hemoglobin construction. A comparison of the effects of phenylhydrazine and venesection appears to support this hypothesis. It has already been noted that the large amounts of iron resulting from hemolysis induced by phenylhydrazine, are stored in the body for future use. The therapeutic use of venesection, on the other hand, removes from the body large amounts of iron and other erythrocyte building-materials, which are then no longer available for the resynthesis of hemoglobin. Reimann and Breuer³ stressed the apparent importance of this factor and felt that it was chiefly responsible for the good results observed in their patients. It is of interest that in five of their seven cases the color index was decreased after venesection.

The observations in patient R. R. indicate that the repeated withdrawal of large amounts of blood may, in time, result in a blood picture similar to that observed in chlorosis and in the iron deficiency anemias. Such an occurrence should not be considered a contraindication to the therapeutic use of venesection for the control of the polycythemic state. If considered advisable, the cell size and hemoglobin content may be increased by the administration of suitable amounts of iron.

SUMMARY

The therapeutic use of venesection has been studied in five patients with polycythemia.

Reduction of the elevated hematocrit values to a normal or slightly subnormal level by means of systematic venesection was accompanied by comparable reduction in red blood cells, hemoglobin, blood viscosity and blood volume and by improvement in circulatory efficiency. The symptomatic and hematologic remissions so induced were maintained for relatively long periods without further treatment. Venesection was followed by increases in the reticulocyte percentage only in those instances in which the tissue

stores of iron were presumably increased as a result of previous blood destruction

The prolonged remissions and absence of reticulocyte increases following reduction of the blood level indicate that venesection under these conditions does not result in significant increase in erythropoietic activity. The relatively long duration of the symptomatic and hematologic remissions observed after venesection is thought to be due to the fact that removal of the large amounts of blood required to produce the desired effect results in the loss from the body of considerable amounts of iron and other potential blood building materials. In several instances decrease in erythrocyte size and hemoglobin content was observed after periods of bleeding.

Systematic venesection appears to be a relatively safe and efficient therapeutic procedure, which compares favorably with other measures used in the treatment of polycythemia.

CASE REPORTS

PERIARTERITIS NODOSA WITH A CASE REPORT

By K. YARDUMIAN, M.D., and R. ROBERT COHEN, M.D., *Pittsburgh, Pennsylvania*

Diffuse vascular lesions with bizarre clinical symptoms of general systemic infection have been reported under various names both in this country and abroad. Because the majority of these cases, unfortunately, have not been diagnosed during the course of the illness, it is apparent that one should keep in mind the possibility of periarteritis nodosa in patients with indefinite symptoms of infection without known etiology and in which all the laboratory studies throw no light on the case.

As one of these, we wish to present the following case of periarteritis nodosa which was missed clinically and even on gross postmortem examination. The final diagnosis was arrived at only after careful study of microscopical sections.

CASE REPORT

Mrs. L. W. (aged 64) was first seen April 12, 1936 with a chief complaint of pain in the legs for the preceding two months. The pain was bilateral, below the knees, especially on the left, cramp-like in character, located in the area of the gastrocnemius, present only when the legs were dependent, and always disappearing when the legs were elevated. There was no change in the color or temperature of the skin. Symptoms referable to the various systems were negative, except for "asthmatic influenza" last winter which kept the patient in bed for three weeks. Examination revealed an aged, white, decrepit female. Skin was dry. Pupils were equal and reacted to light and in accommodation. Ears, nose, throat, heart, lungs, and abdomen were negative. The blood pressure was 158 systolic and 80 diastolic. The extremities were normal in color and their color did not change with changes in position. There was a normal palpable pulsation of the popliteal and dorsalis pedis arteries. There were several varicose veins that filled with dependency and emptied with elevation. Reflexes were entirely normal. The clinical impression at this time was that the pain was circulatory in nature, and due probably to inadequate venous return. On April 13, 1936, the red blood cell count was 3,900,000, white blood cell count 14,350, hemoglobin 55 per cent, polymorphonuclear leukocytes 84 per cent and lymphocytes 16 per cent. The red blood cells were large and irregularly-shaped. The urine was acid, showed no albumin or sugar, and the microscopic examination showed a few pus cells with an occasional granular cast. The patient at this time was put on iron medication (ferrous sulphate) and advised to wear bandages on both legs.

For two weeks, with the bandages, there was no leg pain. On May 2, 1936, however, she began to feel remarkably weak and developed pain and numbness from the elbow to the finger tips of the right hand. This lasted two days. The temperature was 98° F. Examination of the arm revealed nothing abnormal, the heart was found normal and the general examination gave negative findings. The patient was

* Received for publication January 20, 1937.

From the Department of Pathology, Isaac Kaufmann Foundation, Montefiore Hospital, Pittsburgh, Pennsylvania.

put on large doses of yeast with the possibility in mind of a vitamin B deficiency. She felt fairly well for four days, and then, in addition to the great weakness, she showed an inability to walk. She was seen again on May 8, 1936, and at this time complained of sharp shooting pain in both legs, despite the bandages which had been worn constantly. The temperature at this time was 102° F. The tongue for the

FIG 1 Medium sized artery of the pancreas showing thrombosis and canalization. Marked hypertrophy and leukocytic infiltration throughout the layers and intimal degeneration (100 X)

first time was smooth, red and painful. Physical examination otherwise was negative. On May 9, 1936, temperature was still 102°, in addition to the glossitis, there was noted for the first time altered sensation including vibratory sense in both legs with bilateral foot drop. The arms were normal both symptomatically and objectively.

The patient was admitted to Montefiore Hospital on May 10, 1936 with a provisional diagnosis of nutritional anemia, possibly pernicious anemia. On May 11, 1936 she developed tingling and sharp shooting pain in the right arm and two days later in the left arm. Both became progressively worse until there was complete loss of use with disappearance of position sense, pain and thermal sensation, and bilateral wrist drop. The temperature was 101° F, pulse 120, and blood pressure 160 systolic and 90 diastolic. Significant findings were mainly neurological. The tongue was smooth and red. There were diminished reflexes in the upper extremities and absent reflexes of the lower extremities, motor weakness in all extremities especially in the right arm, and atrophy of the hands. There was loss of vibratory and position sense of the lower extremities. Neurological diagnosis, in view of the history and laboratory findings, was posterolateral sclerosis, and the patient was put on liver by mouth and parenterally.

Laboratory findings confused rather than clarified the picture. The blood Wassermann and Kahn were negative, and the spinal fluid examination was negative. Gastric analysis showed hypochlorhydria. The urine showed a trace of albumin, occasional hyaline casts, and 4 to 6 pus cells per field. The blood non-protein nitrogen

was 40 mg per cent. Examination of the urine for heavy metals was negative. On admission the blood examinations showed 63 per cent hemoglobin, 3,430,000 red blood cells, 16,250 white blood cells, and 91 per cent polymorphonuclear leukocytes. Reticulocytes remained less than 1 per cent in spite of therapy, the red cells appeared microcytic and there was no stippling. The blood count did not change materially during the stay in the hospital. Roentgenologic examination of the digestive tract showed no abnormalities.

FIG 2 Arteriole (section of the liver) showing complete obliteration of the lumen, perivascular infiltration with leukocytes. Fibrosis and hyaline degeneration of the media (100 X)

Throughout the patient's three week stay in the hospital the neurological findings did not change. The blood picture remained the same despite liver, vitamin B, HCl, iron, and transfusion of 300 c.c. of blood on three occasions. The major complaint was weakness, and this became progressively more severe. On May 27, the patient had a brief syncopal attack characterized mainly by severe abdominal pain and dizziness while lying quietly in bed. This did not recur. There were daily rises of temperature to 101°, the pulse running constantly between 100 and 120. The patient left the hospital on June 2, 1936 still not definitely diagnosed, the diagnosis of toxic polyneuritis, cause unknown, being retained for want of something better.

At home the patient became progressively worse. She continued to complain of marked weakness, and the neurological picture remained unchanged. Physical examination otherwise remained negative, except for a few rales in both bases. The blood pressure was 180 systolic and 100 diastolic. On June 3, patient began to vomit all food and liquids, lost her voice, and became distended. This continued until June 6, when she died.

Autopsy performed several hours later showed on gross examination an extremely emaciated white adult female about 65 years of age, with marked pallor of the skin and mucous membranes. Superficial glands were not palpable. Abdomen was flat and no palpable tumors were present. The extremities showed marked

atrophic changes of the extensor muscles and thenar and hypothenar eminences of the palms. The abdominal organs were found in normal positions and relations. Patchy discolorations were present in the walls of the ileum and jejunum. Mesenteric lymph nodes were enlarged. The mesentery was studded with minute yellow gray nodules, firm in consistency. Several of these were visible on the serous covering of the

FIG 3 Showing blood vessels of the kidney. The smaller vessels are involved in an inflammatory reaction while the large sized vessels are free from such reaction. (50 X)

bowels. No masses were found. The stomach and large bowel were distended with gas. The liver weighed 1200 grams, had a thick fibrotic capsule, and on cut surface showed mottling of gray areas on a purplish-red background. The spleen was twice normal size, had a thickened capsule, and on cut surface showed marked interstitial fibrosis. The kidneys were atrophic and sclerotic with coarse granulation of the cortex. The adrenals appeared normal. The lungs disclosed old pleuritic adhesions with fibrosis and calcification of both apices. There was edema and congestion of the bases. The heart was pale with flabby myocardium. Excessive subepicardial fat was present. The valves were intact. The coronaries were free from arteriosclerotic changes, though discrete atheromatous patches were seen in the intima of the aorta. The meninges were slightly injected and the cerebral vessels were free from arteriosclerotic changes. There was moderate edema of the brain, but no neoplasm or hemorrhage. The spinal cord showed no gross lesions. The gross anatomical diagnoses were: Marked anemia, chronic myocardial degeneration, congestion and edema of lungs, chronic mesenteric lymphadenitis, ileitis, septic splenitis, edema of brain, bilateral symmetrical atrophy of the upper and lower extremities, and chronic perihepatitis.

Relevant microscopic examination showed marked inflammatory and degenerative changes of medium sized arteries and arterioles in the following organs: liver, kidneys, pancreas, mesentery and spleen. The brain, heart, lungs and adrenals were free from such changes. The nature of the inflammation consisted of several stages of the same process. Some involved the adventitia with marked perivascular infiltration of polymorphonuclear cells. Others involved both the media and adventitia, while in the third group, all three layers were involved with hyaline degeneration, thickening of intima and media with obliteration of the lumen and areas of aneurysmal

dilatation. Sections of the spinal cord did not reveal any cause for neurologic changes in the extremities. Histological diagnoses were periarteritis nodosa of visceral vessels, chronic myocardial degeneration, edema of brain, and chronic nephritis.

FIG 4 Arteriole from mesenteric branches showing marked narrowing of the lumen due to hypertrophy and hyalinization of the intima. Fibrosis of the media and some perivascular infiltration. (50 X)

DISCUSSION

In a review of the literature, the terminology for this condition is found to differ slightly with various authors: periarteritis nodosa, polyarteritis acuta nodosa, and panarteritis. The first description was published in 1865 by Kussmaul and Maier who named the disease periarteritis nodosa and stated that it consisted of inflammatory changes around the adventitia of small arteries and arterioles resulting in multiple nodules along the course of the vessels. Later, Dickson,¹ in 1908, after summing up the literature, differentiated the lesions under two headings. One group was caused by syphilis and was called periarteritis nodosa, while the second group was caused by some unknown infection or toxin and was called polyarteritis acuta nodosa.

As to etiology, Mott and Barton believe that the disease is a luetic manifestation which involves small arteries frequently including the coronaries and occasionally the cerebral vessels. Derick and Hass' report² contains an interesting discussion of the etiology of this disease in which they doubt that periarteritis nodosa is a separate entity at all and believe, in view of their case, that the syphilitic virus is most likely the cause of the arteritis. Their case was one of arteritis of syphilitic origin in a young adult which was diagnosed only after microscopic study of the lesions. They found inflammatory lesions of the small arteries with involvement of all the layers and of periaarteriolar tissues, many vessels showing partial or complete occlusion of the lumina with thickening of the intima and thrombosis. Boyd³ and others, on the other hand, believe that syphilis is not an etiological factor in periarteritis nodosa. The

argument supporting this latter view is that syphilitic lesions are generally found in the elastic type of blood vessels, while periarteritis nodosa is a disease of the muscular type of artery. Though it is true that in several such cases reported in the literature there have been positive serological findings for syphilis, which led the authors to assume that the syphilitic virus was an etiologic factor in their cases, one should not overlook the fact that syphilitic patients may have periarteritis nodosa superimposed as a distinct disease process. Furthermore, even though the literature does not disclose the isolation of a single etiologic factor, aside from the little supported view of infection by unknown filterable viruses, periarteritis nodosa is definitely a clinical and pathological entity.

Clinically, the disease is rare and its diagnostic criteria are not sharply defined. No age is exempt and the occurrence is four to one in males. The clinical manifestations are so varied and bizarre that they may easily simulate a dozen or more diseases. A few of the commonest conditions with which it may be confused are trichiniasis, neuritis, miliary tuberculosis, gastro-enteritis, endocarditis, vascular nephritis and acute abdominal conditions. As to signs and symptoms, those of sepsis predominate, the commonest findings being fever, leukocytosis with or without eosinophilia, moderate to marked anemia, enlargement of the spleen, prostration and loss of weight. Localized manifestations depending on the locations of the main vascular lesions, are anginal attacks in coronary involvement, symptoms of "acute abdomen" in mesenteric vascular lesions, and polyneuritis in neuro-muscular lesions. It follows, therefore, that diagnosis is extremely difficult during life unless there are peripheral nodules. Resection and microscopic examination of which give the diagnosis, or unless, as in the case reported by Bernstein,⁴ biopsy of skeletal muscle discloses the disease. Unfortunately, however, the majority of cases do not show peripheral nodules but, as in our case, only lesions which are confined to vessels of the viscera thus making pre-mortem diagnosis impossible. An autopsy study with careful microscopic examination of the blood vessels is then the only method of diagnosing the disease. In this connection Haining and Kimball⁵ pointed out that in this country we do not perform autopsies frequently enough, for in their excellent review of approximately 150 cases of periarteritis nodosa they found the majority recorded in foreign literature because of the greater number of routine autopsies carried out in clinics abroad.

Pathological findings and descriptions are fairly uniform in the majority of cases recorded. Gross lesions consist of small nodulations varying in size from that of a lentil to a split pea along the affected vessels. These nodules often involve the mesenteric vessels, but when the visceral vessels are the only ones involved, it is very easy to overlook gross changes by the naked eye. The lesions occur in the following organs and tissues in the order of their decreasing incidence: kidneys, heart, liver, gastrointestinal tract, pancreas, mesenteric arteries, muscles, and peripheral nerves. The central nervous system is least involved. Microscopically, various stages of inflammatory reaction and healing are seen in the walls of the small arteries and arterioles. In the early stage, the exudative process consists of polymorphonuclear infiltration of both the media and adventitia. Later, there are proliferative changes of the intima with subsequent thrombosis and occlusion of the lumen with or without dilatation above this site. In the late stages of the disease polymorphonuclear cells are few and

lymphocytes predominate and hyalin and fibrous tissue replace most of the layers of the vessels

SUMMARY

In a case of periarteritis nodosa, clinical observations, postmortem findings and a brief discussion of the subject are presented. The case is of further interest because, despite the mesenteric lesions and small infarctions of the bowel, no acute abdominal symptoms were present. Furthermore, the microscopic studies of the spinal cord did not explain the cause of pronounced neuritis of the extremities. Finally we would like to emphasize the value of routine postmortem examinations, especially in those cases of unknown sepsis, for without postmortem study certainly the diagnosis of this condition will be missed.

A CASE PRESENTING PULMONARY AND OSSEOUS LESIONS PRESUMABLY DUE TO SARCOID

By HENRY F STOLL, M D, F A C P,† *Hartford, Connecticut*

EXCEPT among dermatologists, whose chief interest is confined to the skin manifestations, one rarely hears of sarcoid. The fact that there may be extensive involvement of the viscera and bones in addition to skin lesions appears to be quite generally unknown among internists though such cases were described over 20 years ago. When the skin manifestations are slight or even absent and the other lesions pronounced, a difficult diagnostic problem is presented as the case here reported illustrates.

CASE REPORT

W C, aged 14 years, was referred to me January 16, 1929, for examination because of cough. His general health had been good except that he suffered considerably from sinus disease. It had been observed that the cough was worse when he was having discharge from his sinuses. His appetite was excellent. He was quite free from symptoms other than the cough.

Examination. He was a frail lad with a flat, narrow chest. Height 65 inches, weight 105 lbs. Cervical glands showed slight enlargement. Pulse was 72 and temperature normal. The tonsils did not appear to be infected. With inspiration there was retraction of the lower third of the sternum and also of the epigastrium. There

* Presented at the Detroit meeting of the American College of Physicians, March 5, 1936.

† Deceased.

was a suggestion of increased whisper interscapularly but not enough to be significant. Roentgen-rays of the lungs (figure 1) by Dr Eliot S Cogswell showed some thickening at the roots and a certain amount of fine dappling throughout the lung fields. There were also some clusters of pin-head-size rather "soft" shadows.

FIG 1 June 1929. A fine mottling is evident in the right midpulmonic field and one of less extent in the upper outer part of left lung. Physical signs were negative except for an indefinite D'Espine sign.

I was somewhat in doubt as to the significance of the roentgen-ray findings but felt that they were compatible with a chronic, non-tuberculous type of infection and probably were dependent upon his recurring attacks of sinus trouble.

After ascertaining that the patient was not running a fever, I felt that it was probably not a tuberculous process. I next saw him June 10, 1929 (five months later). He was very well, having been free from sinus trouble and gained 6 lbs. in weight. He exhibited interscapular whisper to the fourth thoracic spine. December 27, 1929 (nearly a year after the first examination), he was very well. His weight was 120 lbs., a gain of 15 lbs. since the first examination. There was still slight enlargement of the cervical glands, but no abnormal signs were noted in the chest. There was some mucopurulent discharge present on the postpharyngeal wall. A month later,

while out of the city he had an attack of pneumonia and is said to have been very ill. He made a good recovery and when seen six months later (June 1930) his weight was 126 lbs—an additional gain of 6 lbs in six months. He appeared then to be in excellent health except that five weeks previously the middle finger of the left hand had begun to swell and to be somewhat painful. At the time of my examination there was a definitely spindle-shaped swelling but the overlying skin was not involved. It did not appear to be particularly painful except on motion. A surprising amount of bone destruction was revealed by the roentgen-ray (Figure 4a).

FIG 2 June 1930 Extensive "snowflake" infiltration of both lung fields somewhat more on the right, with moderate thickening of the hilar structures. Entire absence of physical signs except moderately positive D'Espine sign. General health appeared excellent. Normal temperature.

The roentgen-ray findings of the lungs at this time (figure 2) were even more astonishing. There was extensive, diffuse, soft mottling which was highly suggestive of miliary tuberculosis. From the films alone, one would be quite sure that the lesion was tuberculous, yet he was in excellent health, had gained in weight, was free from fever and with no physical signs of pulmonary disease. The destructive lesions of the bones of the hand were very suggestive of tuberculosis, yet the only pain he experienced was due to a fracture at the site of one of the lesions.

The lung findings were somewhat like the peribronchial, streptococcus pneumonia that occurred during the war, but it seemed unlikely that the lesion as revealed by the roentgen-ray would have persisted for six months. The indolent character of the lesion of the finger was unlike a streptococcus infection. A negative Wassermann appeared to exclude syphilis. I did not know what the pulmonary condition was, nor could I explain the destructive lesion in the bones. Tuberculosis was a strong possibility yet this diagnosis did not ring true.

A protection for the fractured finger was supplied and he was sent to a boys' camp where he was directed to engage in the usual camp activities except that he was to

FIG 3 June 1931 Lungs completely cleared. Hilar structures less dense. This film is even clearer than the one taken in June 1929 (figure 1) which suggests that the process, that was full-blown in June 1930 (figure 2), had really begun when the first film was taken. The attack of streptococcus pneumonia developed about mid-way between films one and two.

avoid all strenuous exercise such as athletic contests, etc. A rest period each afternoon was also prescribed. During the summer he gained 9½ lbs and was free from fever and cough. Roentgen-rays of the lungs at this time showed practically no change but the bony lesion (figure 4b) showed much improvement. There was no pain unless he grasped something very hard with the hand.

In June 1931, after spending the winter in Texas, he was in excellent shape. His

FIG 4 (a) Proximal end of the first phalanx of left middle finger shows a destructive lesion with fracture. The proximal end of the middle phalanx of the ring finger shows a similar but less marked lesion (b) Two months later definite improvement evident (c) One year after a Bone lesions have entirely subsided

weight at this time was 136 lbs 6 oz, a gain of over 31 lbs since the first examination 2½ years before. He was free from cough and the roentgen-ray of the lungs (figure 3) showed them to be entirely clear, better in fact, than at the time of my first examination. It seems probable that the findings noted in the first film, and absent in the last one, were due to the beginning of sarcoid which, by the time the next film (figure 2) was taken, had progressed. When last seen the bone lesions had entirely subsided (figure 4c).

By this time I felt sure that the condition was not tuberculosis though it was not until four years later, when Dr Francis T Hunter showed me the film of a similar case at Massachusetts General Hospital, that I realized that the condition was probably sarcoid. Dr Hunter has since published his case, and the controversial points as to the priority of its recognition and the different views as to the etiology are dealt with in his presentation.

DISCUSSION

Sir Jonathan Hutchinson appears to have been the first to describe one of the skin manifestations of this interesting disease nearly a quarter of a century before Boeck's article appeared. The latter gave a detailed report of the histology and suggested the name "Sarcoid" (sarcoma-like) because of the infiltrative tendency somewhat suggesting the lymphoblastoma group.

Considered first a disease of the skin, it was not until 1902 that Kienbock² reported what he designated as "bone cysts" in a case of sarcoid. In 1915, Kugnitsky and Bittorf³ described visceral lesions showing the same histologic picture in the lungs, bronchial glands and other viscera. By some the condition is considered a manifestation of tuberculosis. Those championing this etiology explain the almost universally negative tuberculin reaction and the failure to find tubercle bacilli in the lesions, to what they term a condition of "anergy"—a relative or complete stage of desensitization. Goeckerman⁴ and Sulzberger⁵ among others, present arguments in support of a tuberculous etiology. The subject of sarcoid was discussed at length by the European dermatologists in 1934. Jens Nielsen,⁶ chief of clinic of the Finsen Institute, Copenhagen, considers it a definite clinical entity. He observed that there was pulmonary involvement (including bronchial glands) in 37 of 46 cases with skin manifestations. In none of them were there clinical or stethoscopic signs of pulmonary involvement.

The condition is benign, torpid and very chronic. Nielsen mentions the possibility of complete resolution but states that the pulmonary lesions are more apt to be stationary. For this reason the case here reported is unique in the rapidity with which the lung cleared. Piérard⁷ says that the pulmonary lesions are characterized by proliferation, they are not exudative in type and there is no tendency to break down and form cavities. Nor do they show a tendency to heal with the production of calcium. There is a lack of peribronchial pattern of lesions, and absence of calcification and of cavity formation. The roentgenogram may resemble miliary tuberculosis, or miliary carcinomatosis, or periarteritis nodosa. In all of these, however, the patient is acutely ill. It is also said to resemble the "sand-paper" mottling of leprosy. Typical sarcoid tissue has been found in the lungs at autopsy. The "bone cysts" (*osteitis multiplex cystica*) are fairly frequent and most common in the bones of the hands and feet. In the case here reported they healed with surprising rapidity as the roentgen-rays show. Kissmeyer,⁸ likewise, considers the disease a specific, chronic granulomatous process, standing midway between tuberculosis and leprosy.

No skin lesion was noted in the patient here described. This should not be interpreted as excluding a small inconspicuous lesion that might easily have been overlooked or thought to be of no consequence. However, members of his family do not recall any skin lesions. Increasing knowledge of the disease may demonstrate that skin lesions are not always present.

Various drugs have been tried with results that are not convincing. In this case, under a regime of outdoor life, with moderate exercise, a great deal of rest and a well-balanced and abundant diet, the recovery was prompt and complete, both the osseous and pulmonary lesions completely resolving.

SUMMARY

A case believed to be sarcoid of the lungs and bones is presented in which skin lesions were absent or minimal. Complete recovery, as demonstrated by roentgenological study, took place with surprising promptness under a regime of somewhat restricted exercise, ample rest and a generous, well-balanced diet.

EDITORIAL

SNAKE VENOM IN HEMORRHAGIC STATES

THE value of moccasin venom in the control of hemorrhage was pointed out by Peck and Rosenthal¹. Peck had earlier found that moccasin venom would produce a refractory state to experimental purpura, or the Schwartzman phenomenon. For a number of years venom of various snakes has been suggested for innumerable diseases, but more definitely in relation to the production of hemostasis by direct application to the bleeding area. It was not until the work of Peck and Rosenthal with the parenteral use of moccasin venom that definite improvement was obtained in certain so-called secondary hemorrhagic states. The exact action of the venom is not known, but it has been assumed that the action is due to a change in the capillary walls resulting in a lessening of their permeability and thus preventing extravasation of blood. Moccasin venom was chosen because it seemed to produce the best results, although some improvement has been obtained with the venom of the copperhead. Cobra venom, since it is largely neurotoxic, has been used with fairly satisfactory results in cases of intractable pain.

Peck and Rosenthal in 1935 reported a series of cases of secondary and primary blood dyscrasias, with particularly good results in that group of diseases associated with some abnormality of the vascular wall. The dose recommended and used most generally is, for patients ten years old or older, an initial subcutaneous injection of 0.4 cc., with a rapid increase in the dose on subsequent injections to 1.0 cc. as a maximal. The reaction of sensitivity, which occurs in most patients on the third or fourth injection, is characterized by a local area of heat, redness, and swelling without much evidence of systemic reaction. At this time desensitization should be carried out by reducing the dose to a minimal quantity, approximately 0.05 cc. This is maintained until all evidence of reaction disappears, at which time the dose may be gradually increased to the full amount of 1.0 cc. twice a week. After hemorrhage has been controlled, the interval between injections may be lengthened to a week or longer depending upon the severity of the original hemorrhagic condition.

Moccasin venom has proved to be of definite value in the treatment of idiopathic epistaxis, bronchiectasis with hemoptysis, and functional menorrhagia, and fairly satisfactory in the treatment of toxic or secondary purpura.

PECK, S. M., ROSENTHAL, N., and ERF, L. A. The value of the prognostic venom reaction in thrombocytopenic purpura, Jr. Am. Med. Assoc., 1936, cvi, 1783-1791.

puric states Peck and Rosenthal also had fairly good results in cases of hereditary multiple telangiectasis, they reported four cases, in two of which very definite improvement was obtained They emphasized the fact that in this particular condition it is important to continue the use of venom over a long period of time In diseases associated with changes in the blood, such as thrombocytopenic purpura, fairly good results were obtained and a definite response was noted in the majority of cases in their group In certain instances improvement was obtained without affecting any change in the blood itself, which would seem to bear out the contention that the action of venom is primarily upon the blood vessels On the other hand, cases of hemophilia, aplastic anemia, and leukemia show little response to venom therapy

In 1936 Watkins and Mussey² confirmed the findings of Peck and Rosenthal in cases of functional menorrhagia, and in 1937 Watkins and Thompson reported a series of twelve cases of essential hematuria, in eleven of which there was cessation of hemorrhage

It would seem, at least at present, from the work that has been done that moccasin venom is of definite value in the control of certain types of hemorrhagic conditions However, the experience with the venom has as yet been too limited to state what the ultimate results will be In some instances recurrences have been noted which may be controlled by resumption of the use of venom, in other instances there seems to be complete cessation of all hemorrhage Until the material has been in use over a longer period of time, and its use confined to secondary hemorrhagic states, it will be difficult to determine its real efficacy in the permanent control of hemorrhage

REVIEWS

Applied Dietetics for Adults and Children in Health and Disease By SANFORD BLUM, M D 408 pages, 24 × 16.5 cm F A Davis Company, Philadelphia 1936 Price, \$4.75

This book has many shortcomings. Published as a new book, it is essentially a revised and enlarged edition of "Practical Dietetics for Adults and Children in Health and Disease" published as a second revised edition in 1926. The present volume follows practically the same formula as its forbear of 10 years ago. It is divided into two parts, the first of which is entitled "Dietary for Adults in Health and Disease", the second, "Dietary for Infants and Children in Health and Disease". Diets are arranged alphabetically according to the title of the healthy or disease state. In comparing the 1926 and 1936 editions there is little to show that advances have been made in the field of dietetics.

To be sure there are new sections as, for example, those on pernicious anemia, carcinoma of stomach, diverticulitis, gall-bladder infection, gonorrhea, hemorrhage from stomach, indigestible foods and combinations, inorganic elements essential to nutrition, pneumonia, salt-free diet, and salt-poor diet. There is also some elaboration of the sections devoted to colitis and diabetes including a discussion of diet with insulin therapy. Occasionally a good deal of common sense is condensed into short chapters such as those devoted to "Dietetics Fads and Fallacies" and to "Vitamins". Incidentally there are practically no changes in Part II of the volume in the 10 year period from 1926 to 1936.

It is difficult to discuss the specific diets offered in this book without being too critical. Perhaps it will suffice to say that many of the diets are far too inadequate and cannot possibly accomplish the end result for which they are prescribed. Very often the choice of foods is without scientific basis. Furthermore it is doubtful whether a person's occupation, be it business or society, woman or college professor, really plays a *predominant* role in the selection of a specific diet. Such notations are dramatic rather than instructive.

In brief, then, this book has not kept abreast of advances in medicine. It represents one of that group of compendiums which in trying to be of service to the busy practitioner often mislead him in his selection of diets as well as in his knowledge of the essentials upon which careful dieting is based.

S M

Dietetics for the Clinician By MILTON ARLANDEN BRIDGES, M D, B S, F A C P Third Edition 1055 pages, 24 × 15 cm Lea and Febiger, Philadelphia 1937 Price, \$10.00

Although the general plan of this third edition has not been changed the book has grown in size from 666 to 970 to 1055 pages through its three editions. According to the author the present volume represents "a relatively new text-book based upon more accurate and up-to-date foundations."

Examination discloses a remarkable and comprehensive treatise. All of the good features of the two previous editions have been retained and in addition the subject matter has been augmented and rewritten so that it becomes one of the most useful reference books in the field of dietetics. The sections prepared by specialists are a feature of the book. Some overlapping and repetition result but these have been reduced to a minimum.

The material pertaining to the mechanics, physiology and chemistry of digestion has been markedly condensed and shorn of extraneous, non-practical discussion. For

convenience, the various disease entities are arranged alphabetically and presented according to the following general plan. Each disease is first the subject of a brief general discussion after which there follows a detailed listing of those foods to be omitted, as well as those allowed in limited quantities. Finally, there is a presentation to the reader, and hence to the patient, of a series of practical edible items of food, readily obtainable, arranged in accordance with the previously outlined principles. Wherever indicated there are added a number of practical medical and culinary suggestions.

The author recognizes that dietotherapy is often empirical and that there are diverse opinions regarding the dietary management of many diseases. Previous editions have been criticized for inconsistencies between the diet and the pathological physiology underlying the diseases under discussion. Such criticisms may, however, be omitted, especially since it is apparent that a sincere attempt has been made to include only those diseases in which, in the opinion of the author and his contributors, diet plays a rôle. With some exceptions they have admirably avoided contentious matter.

The food tables are very comprehensive and well arranged. Under "Distribution of Foods" are included lists showing those foods highest or lowest in Ca, I, Fe, Vitamins A, B, etc., there are also lists showing flatulence-producing foods, fluid foods, soft foods, neutral ash, acid and alkaline-ash foods, etc. It is a comfort to know that data of this kind can be found in one book. Traditional and dietetic evaluation of foods are compared. In the appendix, written in collaboration with Majorie R. Mattice, are listed numerous other tables replete with information concerning food analyses and showing their nutritive, mineral and vitamin values.

The book will be well received because it supplies with authoritative clarity, and in a practical and detailed manner, valuable information in the field of dietetic treatment.

S M

Theory and Practice of Psychiatry By WILLIAM S. SADLER, M.D. 1231 pages, 26 × 18.5 cm. C. V. Mosby Company, St. Louis, Missouri. 1936. Price, \$10.00.

This book was written as a "psychiatric textbook for neuropsychiatric specialists and general practitioners of medicine" and "a reference handbook for psychologists, sociologists, pastors and other professional readers." It consists of 1155 large pages, 2 pages of excellent bibliography, containing almost entirely books rather than articles, 34 pages of glossary and a complete index. It is divided into a good historical introduction which, among other things, outlines the various schools of thought, and five sections.

The first, headed *Theory of Psychiatry*, 233 pages long, is a resume of psychology and psychopathology. It contains a great many definitions, a good deal of illustrative material. Part II, *Personality Problems*, devotes 191 pages to a discussion of personality, classifications of personality, the question of integration, and personality problems at various age levels. Part III, *The Neuroses*, contains an exhaustive presentation of the author's concept of the origin, characteristics, motivations, symptomatology and treatment of these borderline states. Part IV, in 121 pages covers the *Psychoses*, that is the major mental illnesses. The rest of the book, Part V, deals entirely with *Psychotherapeutics*.

The book concerns itself primarily with the study and treatment of non-institutional patients of the sort that may be expected to present themselves to general practitioners. It is exceedingly readable. This is a distinct tribute to a volume of this size. One's interest does not lag at any point, however much one may disagree with the author. Early in his writing he tells us that he personally agrees in most respects

with orthodox views, but he here sets forth utilitarian concepts he finds clinically useful. He is certainly resourceful, never loses sight of the broader aspects of the problem with which he has to deal, and does not hesitate to make use of any means to help restore his patient to health.

We conceive it to be the duty of a reviewer in a special field to give individuals outside his particular branch of medicine his reactions to a book which entirely concerns itself with that special field. We have read most of this large volume twice and have been unable to escape the feeling that this might have been an enduring classic if it had been condensed into 250 or 300 pages. There is much throughout the book which is exceedingly worthwhile. It is a volume which should be read in its entirety or not at all. Otherwise, it is likely to give rise to distinct misunderstandings. An example is the statement on page 477, in which we are told to "laugh heartily at his fears and get him (the patient) to join in the laughter. Ridicule is the master cure for fear." Dr. Sadler is too good a psychiatrist and to kindly a man to imply that we should ridicule the patient himself. In many places he explicitly warns us against doing so. This is typical of many instances throughout the book.

There are many repetitions, there are too complex classifications of personalities—almost as many as there are individual case histories presented. There is very little effort to group them. One gets the impression of hair-splitting minor variations. The chapter on Classifications of Personality, for example, contains a Psychosociologic Classification into 12 groups under such headings as Deficient Personality, Perverted Personalities, Criminal Personalities, etc., an Intellectual Classification of Personalities, a Sociologic Classification of Personalities, Temperamental Types of Personality, Endocrine Classification of Temperaments, including such statements as

"The Gonad-Dominant Type—This type is generally found to be secretive, sly and receptive. They are not always outwardly sensual appearing, but thorough acquaintance reveals that their entire lives are motivated by the sex urge", a Sensory-motor Classification, a paragraph on Behaviorism and a short section entitled, Other Classifications. We feel that any such discussion as this would be very likely to hopelessly befuddle most individuals and might prove exceedingly misleading to some of the groups, such as pastors and sociologists, for whom the book is written. There are too many vague descriptions of personality distortions or of neurotic pictures. Throughout the book he speaks of such things as Master motives, Master psychobiologic drives, the psychology of self-deception, discussions of self-realization, moral maladjustment, cosmic maladjustment and realizing personality potentials which seem to us to have little place in a psychiatric textbook, tinged as they are by more than a trace of semi-religious exhortation similar to the type found in so many of the "Know Thyself," "Quest for Happiness" popular psychologies which have flooded the book-stalls in the past few years.

The section on Psychotherapeutics contains a great many exceedingly helpful suggestions and technics. Chapters 68, 69, 72 and 73 are good. There is a timely and worthwhile chapter on the teaching of psychiatry and psychiatrists. Chapter 74, listing and explaining various philosophies of life, is interesting, but the whole 230 pages of this section are so interlarded with what amounts to "pep talks," slogans such as "Hold the fort," "Sand the track," "Play the game square and take the score like a man" as to create a great deal of difficulty in separating the wheat from the sort of chaff best illustrated by his instruction as to the technic of mastering fear, which (page 974) consists in getting the patient to assume the following attitude: 1 Do not fear it, 2 Do not fight it, 3 Do not disown it, 4 Do not try to run away from it, 5 Utilize fear as a fight stimulus, 6 Refuse to foster fear curiosity, 7 Unmask fear, 8 Avoid the fear habit. The tendency to moralize and to make appeals to one's better self are constantly present as in "Conscious conflict, when viewed squarely and faced bravely, is the battle cry of one's better self, calling for the mobilization of all

the powers of the idealism of the personality for the purpose of effecting the psychic conquest and subsequent ethical and moral elevation of one's natural emotional impulses and innate biologic urges" We respectfully submit the point of view that few of us are innately equipped to exhort our patients with sufficient conviction to even send them away from our offices with a temporary glow of well-being, let alone effect lasting benefit

H M M

Tissue Immunity By R L KAHN, M S, D Sc 707 pages, 23.5 × 17 cm Charles C Thomas, Baltimore, Maryland 1936 Price, \$7.50

This book presents a thorough exposition of the author's ideas on the rôle the tissues in general play in resistance to infection. There is no attempt to substitute one theory of immunity for another, but merely to extend and enlarge the concept of the immunological responses to bacteria and other antigens. These responses are considered a physiological function of all cells and are believed to have their evolutionary origin in parasitism. Tissue immunity is not only philosophically discussed but many experiments are described in substantiation of the author's views. These demonstrate the reaction to an antigen of various tissues in the non-immune state, in the naturally immune animal, at different stages in the rise and fall of acquired immunity, and finally in the condition of "disimmunity." The clinical significance of these responses is given full consideration. Though it is not impossible that exception will be taken to some of the conclusions drawn from the experiments, this book is undoubtedly an important and stimulating contribution to the literature on immunology and one that may be unhesitatingly recommended both to the clinician and to the specialist in this field. It is, however, regrettable that the style of presentation is not more pleasing.

F W H

Heart Disease and Tuberculosis By S ADOLPHUS KNOPP, M D 108 pages, 20.5 × 14 cm The Livingston Press, Livingston, New York 1936 Price, \$1.25

The author has played an active part for many years in anti-tuberculosis work. In this small book he gathers together in brief form many rather disconnected observations upon the present status of preventive methods in both diseases. The importance of diaphragmatic breathing as a preventive and even a curative method is heavily stressed.

M C P

Modern Urology By HUGH CABOT, M D 1813 pages, 24.5 × 17 cm Lea and Febiger, Philadelphia 1936 Price, \$20.00

Cabot's *Modern Urology* is well named for it brings up to date every phase of urology and does it very efficiently. The chapters are written by different authors who are authoritative and who well represent urology in America. The book is in two volumes, is well edited, and is profusely illustrated. The first volume is divided into six sections dealing with the lower urinary tract. It contains a chapter dealing with methods of diagnosis which is unusually informative and a chapter on transurethral resection of the prostate gland, which, while enthusiastically written, is nevertheless a well balanced description of the procedure and its results in the hands of the urologists in this country most proficient in its use. The open types of operation on the prostate gland are also very well described by able and experienced surgeons.

The second volume is divided into four sections, dealing with conditions in the bladder, ureters and kidneys. The chapters on stone present the newer conceptions of stone formation. The article on anomalies of the kidneys and uréters is probably the best and most complete information on this subject that has appeared in years. Tumors of the kidney have been particularly well presented, and the classification of these tumors which is offered is based on sound reasoning. The last section deals with radiation therapy of tumors of the genito-urinary tract. This section discusses the radiosensitivity of cancers and classifies tumors accordingly, and indicates the manner in which these various tumors are to be radiated and the results in a large experience. It is a very valuable section.

Cabot's *Modern Urology* is a book that every urologist should possess. It should also be accessible to general surgeons, general practitioners and students as the best encyclopedia of urology.

COLLEGE NEWS NOTES

THE NEW HEADQUARTERS OF THE AMERICAN COLLEGE OF PHYSICIANS

In accordance with action initiated by the Board of Regents and the Board of Governors of the College at the 1936 Annual Session, the College acquired by purchase the former residence of Charles J. Eisenlohr at 4200 Pine Street, Philadelphia. The permanent headquarters building is illustrated herewith. The building occupies a plot of ground approximately two hundred feet square, bounded by South Forty-Second Street on the east and by Pine Street on the north. The grounds are beautifully landscaped, with many attractive shrubs, evergreen and deciduous trees. The

FIG 1 Main entrance

FIG 2 View of the garden and building from the south

FIG 3 Reception hall and staircase

FIG 4 Secretary's office

FIG 5 Executive Secretary's office

house was built in 1906-07 from the architectural plans of Horace Trumbauer, who has attained an enviable position as an architect from the many beautiful and practical buildings he has designed, among them being the new Duke University at Durham, N C The following architectural details of the College's new home may be of interest to the members

"In style it is based on the tradition of the late Eighteenth Century French Architecture of the period of Louis XVI In composition it consists of a main mass and a lower wing The main part is sub-divided into a central portion with a pavilion on each end, accented on the first floor with tall windows surmounted by pediments supported on consoles The main walls are two stories in height and are

FIG 6 Lounge and Board room

crowned with rich cornice and high mansard roof, this latter being metal crested and terminating in moulded finials

"The main body of the walls is constructed of gray buff brick accented by the terra cotta cornice, window, and entrance and porch details

"The property is surrounded by a wrought iron fence designed in the same general style as the house and is recalled in the house by the wrought iron doors and window grilles at the main entrance and doors to the south porch

"The decorative treatment of the interior is consistent with the style of the exterior and again follows the Louis XVI style The rooms are paneled in wood with decorative plaster cornices and marble mantels"

The location is but a few squares removed from the University of Pennsylvania and the Philadelphia College of Pharmacy and Science Excellent transportation facilities are available through surface and subway-surface trolley lines, furthermore, it is within convenient distance of the new West Philadelphia Station (Thirtieth

Street) of the Pennsylvania Railroad and the Twenty-Fourth Street Station of the Baltimore and Ohio Railroad

The house answers the long pressing need for adequate offices, committee rooms and a Board room for the College. With a minimum of alteration, the house has been admirably arranged for the work of the College. Spaces are available for the College Library of publications by members, for various meeting rooms and for social gatherings of members. On the second floor are available rooms in which examinations of the American Board of Internal Medicine may be held when these examinations are scheduled for the Philadelphia territory, also rooms where members may conduct private conferences when in Philadelphia.

The members of the College are cordially invited to visit and inspect the new College building and to use it for their headquarters when passing through Philadelphia.

THE COLLEGE LIBRARY OF PUBLICATIONS BY MEMBERS

Considerable progress has been made in establishing a College Library of books of which our members are the authors. This Library, in a sense, is a memorial library to our members. A general medical library, other than one composed of publications by the members, is scarcely justified, because there are so many other general medical libraries available in Philadelphia.

A little booklet indexing all the books that have been donated to the College Library will be ready for distribution at the College Booth at the St. Louis Session, April 19 to 23.

We gratefully acknowledge the following recent contributions:

Books

- Dr. Ray M. Balyeat (Fellow), Oklahoma City, Okla., one autographed book, "Allergic Diseases: Their Diagnosis and Treatment",
- Dr. Charles A. Doan (Fellow), Columbus, Ohio, one autographed book, "Clinical Implications of Modern Physiologic Hematology",
- Dr. Harry A. Pattison (Fellow), Livingston, N. Y., one autographed book, "Edward Livingston Trudeau, A Symposium" (with Lawlason Brown, Allen K. Krause and Charles G. Trembley),
- Dr. Willard J. Stone (Fellow), Pasadena, Calif., one book, "Bright's Disease and Arterial Hypertension".

Reprints

- Dr. M. Coleman Harris (Fellow), New York, N. Y.—1 reprint,
- Dr. Samuel E. Munson (Fellow), Springfield, Ill.—1 reprint,
- Dr. Robert Sterling Palmer (Fellow), Boston, Mass.—3 reprints,
- Dr. John W. Shuman (Fellow), Los Angeles, Calif.—1 reprint,
- Dr. Edward L. Turner (Fellow), Nashville, Tenn.—12 reprints,
- Dr. Hyman I. Spector (Associate), St. Louis, Mo.—4 reprints,
- Dr. Hugh Stalker (Associate), Grosse Pointe, Mich.—1 reprint.

Dr. Elliott P. Joslin (Fellow), Clinical Professor of Medicine, Harvard University Medical School, Boston, delivered the ninth annual Ranson Lecture at Northwestern University, February 3, on protamine insulin.

Dr Samuel M Bittinger (Fellow), assistant superintendent of the North Carolina Sanatorium, Sanatorium, N C, will be the director of the Western North Carolina Sanatorium now under construction, near Asheville Dr Paul P McCain (Fellow), superintendent and medical director of the North Carolina Sanatorium for the Treatment of Tuberculosis, will have general supervision over the new institution

Dr Roscoe L Sensenich (Fellow), South Bend, Ind, has been elected president of the Northwest Medical Conference

Dr Thomas Parran (Fellow), Surgeon General of the U S Public Health Service, delivered the Gehrman Lectures at the University of Illinois College of Medicine during March on the subjects "Health as a Factor in Social Security," "Industrial Hygiene" and "Syphilis"

Dr Alfred R Masten (Associate), Denver, has been appointed director of a newly created division of tuberculosis control under the Colorado State Board of Health

Under the auspices of the Fulton County (Ga) Medical Society, Dr Henry W F Woltman (Fellow), Professor of Neurology, University of Minnesota Graduate School of Medicine, delivered the E Bates Block Memorial Lecture in Atlanta, January 28, on the subject, "Postoperative Neurologic Complications"

The fifth annual graduate clinic of the George Washington University School of Medicine, Washington, D C, was conducted during February, with the following Fellows contributing

Dr William E Clark, "Duodenal Ulcer",

Dr Walter A Bloedorn, "Relation of Clinician and Pathologist",

Dr Roger M Choisser, "Sudden Death A Clinical Pathologic Consideration with Case Presentations"

Dr Henry J John (Fellow), Cleveland, Ohio, was the recipient of the Eisenman Award of the Cleveland Jewish Welfare Federation at a meeting on February 4, the award being made in recognition of his work for diabetic children in Cleveland

Dr Edward B Krumbhaar (Fellow), Philadelphia, Pa, has been elected vice president of the College of Physicians of Philadelphia

DR WILLIAM ALLANSON WHITE

OBITUARIES

WILLIAM ALLANSON WHITE

William Allanson White (Fellow), an eminent physician, a pioneer psychiatrist of international renown and a gallant gentleman, died on March 7, 1937, in his apartment at St Elizabeths' Hospital of which he had been Superintendent for the past thirty-four years

Dr White was born in Brooklyn, New York, on January 24, 1870, graduated from Cornell University in 1889, and from Long Island Medical College in 1891. In the following year he was appointed second Assistant Superintendent of the New York State Hospital for the Insane at Binghamton

In 1903 President Theodore Roosevelt appointed Dr White Superintendent at St Elizabeths, then known as the Government Hospital for the Insane at Washington, D C, a position which he held at the time of his death. He was Professor of Psychiatry at George Washington University, the U S Army Medical School, the U S Navy Medical School, and until 1932 at Georgetown University School of Medicine, a position which he relinquished because of pressure of work. He was a Fellow of the American College of Physicians, a member of the National Research Council, a member of the Board of Directors of the National Committee for Mental Hygiene, Ex-President International Committee for Mental Hygiene, Councilor, Medical Council, U S Veterans Administration, member and former Secretary Federal Board of Hospitalization, Ex-President American Psychiatric Association, American Psychopathological Society, American Psychoanalytic Society, Psychoanalytic Society of the District of Columbia, The Society of Nervous and Mental Diseases, Washington, D C, Medical Society of the District of Columbia, American Medical Association, American Institute of Criminal Law and Criminology, American Neurological Association, American Anthropological Association, Tri-State Medical Association, Washington, D C Psychopathological Association, New York Psychiatric Association and many other learned Societies and Associations

Dr White was a prolific writer, his articles appearing in the leading medical and scientific journals of this and many foreign countries. He was the author of the following books

"Insanity and the Criminal Law" (Macmillan)

"The Meaning of Disease" (Williams and Wilkins)

"Mechanisms of Character Formation" (Macmillan)

"Principles of Mental Hygiene" (Macmillan)

"Mental Hygiene of Childhood" (Little, Brown & Co)

Textbook on Nervous and Mental Disease—with Jelliffe (Lea and Febiger)

- "Outlines of Psychiatry"—14th Edition (Nervous and Mental Disease Publishing Company)
- "Mental Mechanisms" (Nervous and Mental Disease Publishing Company)
- "Introduction to the Study of the Mind" (Nervous and Mental Disease Publishing Company)
- "Essays in Psychopathology" (Nervous and Mental Disease Publishing Company)
- "Lectures in Psychiatry" (Nervous and Mental Disease Publishing Company)
- "Thoughts of a Psychiatrist on the War and After" (Paul B Hoeber)
- "Twentieth Century Psychiatry" (W W Norton & Co)
- "Modern Treatment of Nervous and Mental Disease" With Dr Smith Ely Jelliffe (Lea and Febiger)
- "Crimes and Criminals" (Farrar and Rinehart)
- "Foundations of Psychiatry" (Nervous and Mental Disease Publishing Company)
- "Forty Years of Psychiatry" (Nervous and Mental Disease Publishing Company)
- "Medical Psychology" (Nervous and Mental Disease Publishing Company)

It is difficult now and will be increasingly so in the years to come for the medical men of the National Capitol who had come to rely upon Dr White's wise counsels in trying situations affecting public policy, as well as in matters medical, to realize that he has gone forever from among us

His wide and constant contacts with men in public life and his long experience in matters before Congress enabled him to render valuable service to local medical organizations as well as to many other such organizations throughout the land. Bills in Congress affecting the healing art were constantly submitted to Dr White for his opinion, and many were the hidden pitfalls which his keen analytical mind discovered. No day was too crowded for him to pause and respond to the call for aid from a brother practitioner. His friends often marvelled that he could afford the time to attend conferences on civic as well as professional matters. As Superintendent of St Elizabeths Hospital he was responsible for the well being of approximately six thousand patients and a thousand employees, in addition to the direction of his professional staff. Dr White would have had little interest in an Institution devoted largely to merely custodial care of the mentally afflicted. The goal set by St Elizabeths during his Superintendency was curative treatment.

While a student at Cornell he resolved, as Herbert Spencer has asserted, that it is possible for an intelligent man to acquire a comprehensive knowledge of every subject. He recognized the tremendous personal effort that

would be involved in even approximating the accomplishment of this ideal. In setting himself to the task, he determined that while mental medicine should command his prime attention, a wide acquaintance and familiarity with other sciences and with organized effort for political and social advancement would enable him to better serve the cause of his chosen profession.

Thus we find him a voracious reader, not getting books from libraries but purchasing them so that they would always be at hand for ready reference. Astronomy, anthropology, medieval and modern art and architecture, engineering, the principles of the law, sociology, political economy, these are some of the subjects which were read with avidity, and absorbed by his wonderful intellect. Soon it was apparent that important works in foreign tongues must be read in the original. To acquire this facility he enrolled in a foreign language school, mastering German and acquiring a working familiarity with French, Spanish and Italian.

All the while he was devoting himself assiduously to his profession. Recognizing that European Universities and laboratories were forging ahead in the diagnosis and treatment of various forms of mental disorder, he spent several summers as a student at the feet of the masters and in laboratory research. On each return he would apply to the great work at St. Elizabeths important results of his foreign studies and observations.

It was becoming apparent that his understanding of the mental processes of others was made clearer by reason of his general knowledge of other subjects. He must keep abreast of all things touching human life that he might definitely accomplish something for the mentally afflicted.

The field needed many more workers, men and women who would devote themselves intelligently and whole-heartedly to the high purpose for which he was giving his life. These must be thoroughly trained physicians, capable of working with him in the field of mental medicine. Already, with Jelliffe he had written the *Outlines of Psychiatry*, destined to be a standard textbook in all medical schools of the country. To supplement this and to urge young physicians to enlist in the cause he lectured to students in Washington and New York, wrote an astounding number of books and articles for professional journals, talked before important gatherings throughout the land, and personally developed at St. Elizabeths several score of men and women who attained superintendencies and ranking positions in other hospitals.

Men marveled that he could accomplish so much. The extent of his professional activities seemed boundless. A happy orderliness in all affairs was of material aid in the effectuation of his plans and ambitions. Required by law to live at St. Elizabeths, he made it a practice whenever possible to spend three or four evenings away from the Institution. During these periods he was outside the atmosphere of the abnormal, was circulating among normals, enjoying a change of surroundings, refreshing his mind often at the theatre of which he was a devotee. When so refreshed, he

was ready for more work, and probably the great majority of his books were written between midnight and three in the morning. Then, to use his own confession, he was ready to enjoy the "profundity of sleep."

He introduced military psychiatry in this country, was one of the first Superintendents to place female wards under women physicians, was one of the organizers of the Mental Hygiene movement, attended sessions and took conspicuous part in the activities of many medical societies. The positions and honors that came to him were not regarded as personal, they were concrete evidence that more and more the members of his own profession were recognizing the fact that psychiatry was an important branch of medical science, that the problem of the mind diseased must be kept close to the hearts of all physicians.

There was no spark of professional jealousy in his makeup. He was working for those less fortunately endowed, and all that he acquired was freely given to his associates. He was the recognized leader, but he labored shoulder to shoulder, hand in hand, and in genuine companionship with his co-workers.

When he passed on, it was noticeable that men and women in all walks of life, with no particular personal acquaintance with him but legion in numbers, mourned the loss of one whom they held in personal regard. Why should this be so? Why should persons whom he knew not by name nor by sight feel that they had sustained a loss? The answer lies in the fact that the people long since had been convinced of the sincerity of his desire and purpose to serve his fellow man.

His friend and personal counselor, Frederick A. Fenning of the Washington Bar, has collaborated in the preparation of this paper that expression may be given to some of the underlying motives, to a few of the purely personal aspects of one with whom he enjoyed intimate association for more than thirty-three years.

WILLIAM GERRY MORGAN, M.D., F.A.C.P.,
Secretary General

DR. ELIAS HUDSON BARTLEY

Dr. Elias Hudson Bartley (Fellow), Brooklyn, N. Y., died January 12, 1937, of senility. Dr. Bartley was one of the Founders of the American College of Physicians, and, therefore, had been a Fellow since 1915. He was early elected a member of the Council, now known as the Board of Regents, of the College, and the early Minutes of the organization show that he took a very active part.

Dr. Bartley was born at Bartley, N. J., December 6, 1849, later removing to Princeton, Ill., where he attended the public schools. He received his Bachelor of Science degree from Cornell University in 1873, taught in the Princeton High School for a year and then became Professor of Chemistry at Swarthmore College, Swarthmore, Pa., for three years. He then pur-

sued his medical training at the Long Island College Hospital, graduating in 1879. Immediately thereafter he was appointed Assistant to the Chair of Diseases of Children, Lecturer in Chemistry and Instructor in Chemical Analysis at the Long Island College Hospital. He was promoted to the Professorship of Chemistry and Toxicology in 1886, continuing in that capacity until 1901. Coincident with this, he developed the Department of Pediatrics. He was professor in that department from 1901 to 1915. He was Acting Dean of the Faculty from 1915 to 1917, when he retired as Emeritus Professor of Chemistry and Pediatrics. He was Chief Chemist for the Brooklyn Health Department from 1882 to 1888, a member of the Kings County Board of Pharmacy from 1892 to 1898, and Consulting Pediatricist to the Long Island College Hospital, Methodist Hospital and the Kingston Avenue Hospital, all of Brooklyn, and the Southside Hospital, Bay Shore. For several years he was Chief of the Department of Pediatrics at the Brownsville and East New York Hospital. He was a member of the U. S. Pharmacopeia conventions in 1890, 1900, 1910 and 1930. During his term as Chief Chemist to the Health Department of Brooklyn he organized the first systematic attempt to inspect and control the milk supply of that city. This met with much opposition, but by persistent work and the building up of public sentiment, results began to be obtained. It is said that cholera infantum immediately decreased and finally disappeared. The results he obtained constitute a striking example of public health education backed by the medical profession. In 1902, through the efforts of the Medical Society of the County of Kings, the first Milk Commission was organized, with Dr. Bartley as its chairman. From 1892 to 1902 Dr. Bartley was Dean and Professor of Organic Chemistry at the Brooklyn College of Pharmacy.

The Long Island Medical Journal was founded by Dr. Bartley while he was President of the Associated Physicians of Long Island. In 1912 he was elected President of the Medical Society of the County of Kings. He was a member of the Medical Society of the State of New York, a Fellow of the American Medical Association and a member of its House of Delegates, 1909-10, a member of the New York Academy of Medicine, the Brooklyn Pediatric Society, the Brooklyn Pathological Society and many other organizations. In addition to his Fellowship and Councilorship in the American College of Physicians, he served at one time as a Vice President.

Dr. Bartley was the author of many published articles and of a "Text-book on Medical and Pharmaceutical Chemistry," of which seven editions appeared between 1885 and 1909. He was also the author of a "Manual of Clinical Chemistry," which was published in three succeeding editions.

Although of late years his contacts with the College and his activities have necessarily been diminished, the spirit of his service remains

DR JAMES P McKELVY

Suddenly stricken while en route to Arizona to spend the winter, Dr James P McKelvy of Pittsburgh, Pa, died in St Luke's Hospital, Kansas City, Missouri, on January 28, 1937

Born in Wilkinsburg, Pa, a suburb of Pittsburgh, December 1, 1869, his preliminary education was obtained at the local public schools and the Pittsburgh High School After graduation from the latter he studied chemistry at Columbia University and then returned to Pittsburgh to become associated with the manufacturing firm of McIntire-Hemphill Company as chemist

After three years Dr McKelvy returned to Columbia University to enter the College of Physicians and Surgeons, from which he graduated in 1901 He served internships for two years at the Roosevelt Hospital and the Sloan Maternity Hospital and then returned to Pittsburgh to take up the practice of medicine

Dr McKelvy was attending physician to the Allegheny General Hospital from 1907 to 1925 and Physician-in-Chief from 1925 until his death He was a member of the Board of Managers of the William H Singer Memorial Research Laboratory from the time of its establishment in 1916

President of the Allegheny County Medical Society in 1919, he was also a member of the Pennsylvania State Medical Society, a Fellow of the American Medical Association and the Pittsburgh Academy of Medicine Elected to Fellowship in the American College of Physicians in June 1917, he was almost a charter member of our organization

Dr McKelvy belonged to the Pittsburgh Club, Oakmont Country Club, Allegheny Country Club, Fox Chapel Country Club, University Club and the Seaview Golf Club of Absecon, N J

He was a member of the Sixth United Presbyterian Church of Pittsburgh

Surviving are his son, Mr William M McKelvy, a brother and three sisters

E BOSWORTH MCCREADY, M D, F A C P,
Governor for Western Pennsylvania

DR JAMES LESLIE BUSBY

Dr James Leslie Busby, a Fellow, died in Pasadena on February 18, 1937 Dr Busby was born in 1890 in Millersport, Ohio He received his M D degree from Ohio State University in 1913, was an intern in St Clair Hospital, Columbus, in 1913 and 1914 and practiced in Shelby and in Columbus from 1914 to 1918 when he joined the Medical Corps of the Army He was assistant chief medical advisor in the Bureau of War Risk Insurance and for two years chief of the section of medicine and surgery in the United States Public Health Service He entered the Mayo Foundation January 1, 1923 He was made an associate in medicine January 1, 1925, and was

an instructor in medicine from 1927 to 1929. He left the Mayo Foundation in August 1929 to practice medicine in Pasadena.

Dr. Busby was a member of the senior staff of the Los Angeles General Hospital and an Associate Professor of Medicine in the College of Medical Evangelists. He was a member of the American Medical Association, the Southern California Medical Association, the Los Angeles Clinical and Pathological Society, the Alumni Association of the Mayo Foundation for Education and Medical Research, and a Fellow of the American College of Physicians. He was on the staff of the Huntington Memorial Hospital and St. Luke's Hospital in Pasadena and chairman of the Medical Advisory Board of the Ruth Home in El Monte, California. Dr. Busby was widely and well known. He enjoyed a large practice and had many professional, civic, and social connections. He will be greatly missed in his community. He is survived by his wife, Louise Busby, and two children.

EGERTON L. CRISPIN, M.D., F.A.C.P.,
Los Angeles, California

DR. DAVID G. GHRIST

Dr. David G. Ghrist, a Fellow of the College, died in the Good Samaritan Hospital in Los Angeles on February 3, 1937, from pneumonia following an attack of influenza.

Dr. Ghrist was born in Ames, Iowa, in 1898. He received an A.B. degree from Stanford University in 1921 and an M.D. from Harvard University in 1925. He had an internship in the Los Angeles General Hospital from 1925 to 1926, which was followed by a period of private practice until April 1, 1927, at which time he entered the Mayo Foundation as a Fellow in Medicine. He was appointed a first assistant in his clinical division of medicine April 1, 1929. In 1930 he received a degree of Master of Science from the University of Minnesota.

Dr. Ghrist went from the Mayo Foundation to Los Angeles in October 1930, where he established himself in the practice of internal medicine. His training, ability and personality enabled him to build up a large and satisfactory practice in his chosen field.

Dr. Ghrist was a member of the Beta Theta Pi and Nu Sigma Nu fraternities. He was a member of the Staff of the Good Samaritan Hospital and of St. Vincent's Hospital, and a member of the Association for the Study and Control of Rheumatic Diseases. He was Secretary and Treasurer of the Southern California Medical Association and was Associate Professor of Medicine in the University of Southern California Medical School.

Dr. Ghrist was an able physician whose sterling qualities were admired by all who knew him. He is survived by his widow, Winnefred Ghrist, and by one daughter.

EGERTON L. CRISPIN, M.D., F.A.C.P.,
Los Angeles, California

DR COLLINS HICKEY JOHNSTON

Dr Collins H Johnston (Fellow), died suddenly in his home, Grand Rapids, Michigan, on December 29, 1936. He was seventy-seven years old and was actively engaged in his professional work until the day of his death.

Born in Detroit, Michigan, he graduated from the University of Michigan (Lit.) 1881, (Medicine) 1883, and came to Grand Rapids a few years later. Throughout his busy life he maintained a great interest in the scientific side of medicine. A real student with excellent background, he kept up with the newer things in medicine throughout his long professional life, by means of frequent trips to teaching centers both in this country and abroad. A general practitioner, he had, at different periods, shown very special interest in Pediatrics and Tuberculosis. The special societies to which he belonged attest this interest. He was a member of the American Clinical and Climatological Association, Michigan Trudeau Society, Central States Pediatric Society, and others. At one time he was a member of the House of Delegates of the American Medical Association, and was an ex-president of the Kent County Medical Society. He was on the Visiting Staff of Blodgett Memorial Hospital and Honorary Chief of Staff of D. A. Blodgett Home for Children.

In civic affairs and in his church (Episcopal) he was always an active and willing worker, giving of himself willingly and untiringly. Measures for the promotion of public health always had his interest and for years he campaigned for a pure water supply, and was Chairman of the Medical Milk Commission for safe and good milk. He was largely responsible for the establishment of the Grand Rapids Clinic for Infant Feeding, one of the earliest clinics for this purpose established in the country.

Dr Johnston will be remembered by his colleagues as an aggressive, industrious and most competent practitioner. His constant, never failing effort to keep abreast of the times, his interest in all things pertaining to medicine, can well serve as a real example to the younger generation.

OF DOCTOR JOSEPH HERSEY PRATT

PROBLEMS OF ENDEMIC GOITER *

By FRIEDRICH VON MUELLER, *Munich*

THE two goiter conferences held at Berne in 1928 and 1933 revealed to the trained eyes of the participants the fact that in different countries, as, for example, in Munich, Berne, Vienna, Oslo and Utrecht, the clinical course and microscopic appearance of endemic goiter are quite variable. One dare not, for example, carry over and apply the experience of McCarrison or the Scandinavian countries to the endemic malady of the subalpine regions or, perhaps, the North American areas. The fundamental studies of the Swiss investigators and recently those of Dieterle and Eugster have shown that endemic goiter is locally confined to certain regions, villages and even houses. Further, it is not peculiar to the higher altitudes but rather occurs in the subalpine regions and gravelly areas about the streams which flow northward and southward from the Alps, as well as in the diluvial formations which represent deposits of the glacial epoch. Cretinism, the most baneful result of thyroid insufficiency, also occurs in the midst of this endemic goiter region. Endemic goiter in Europe is by no means entirely limited to the subalpine regions, for isolated areas where goiter is common are also found in Holland, along the North Sea coast, as well as in the valleys of the Oder, the Vistula and even the Saar. In the latter goiter areas, however, there is a striking absence of cretinism. The goiter which occurs in those endemic regions near the seacoast is, however, characterized by a great sensitiveness to iodine. Theodore Kocher has pointed out that true, genuine Basedow's disease occurs quite rarely in the subalpine endemic areas, while in the lowland plains of North Germany (i.e., in a country which is nearly free from goiter) it occurs not only much more frequently, but also in a much more malignant form. I have, myself, encountered the more acute forms of Basedow's disease which threaten the life of the patient, only in the regions of Northern Germany.

* Received for publication March 10, 1937

Reports from the subalpine endemic regions indicate that even in new-born infants the thyroid glands are distinctly larger and heavier than those of the new-born in North Germany. Indeed, actual goiter occurs in the new-born in the subalpine regions. These thyroid enlargements of the new-born ordinarily present the picture of "parenchymatous" goiter, that is, with branching sacs rich in cells without follicle formation and without colloid. Further, experience has shown that even in endemic regions goiter of the new-born does not occur if the mother is given iodine during pregnancy. I possess such preparations of the thyroid gland of new-born infants from the endemic regions which were taken from children whose mothers had been treated with iodine and I was able to prove to my own satisfaction that in these cases the thyroid had a completely normal appearance, with follicles properly filled with colloid.

It is certain that endemic cretinism is closely associated with pathological changes in the thyroid gland. In about 90 per cent of the cases this takes the form of nodular goiter, often of considerable extent and showing severe degenerative changes. In about 10 per cent of the cases of cretinism there is no goiter, but rather we find almost complete absence of the thyroid. In these cases the thyroid gland is either quite undeveloped or, as the result of intra-uterine degenerative processes, it has been reduced to a small and compact solid mass. The most severe cases of cretinous degeneration are these with *athyrosis*.

It has further proved to be the case that in most cases of cretinism the mother likewise was goiterous. It cannot be concluded from this that both goiter and cretinism rest upon an inherited basis. The more probable conception is that the noxa of goiter, *the nature of which is unknown* to us, has acted during the course of the pregnancy, not only on the mother but also on the child in utero. As a consequence of our above mentioned experiences with the congenital goiter of the new-born, it may also be hoped that normal development of the thyroid gland may be achieved by means of the administration of iodine to pregnant women. In other words, the fight against cretinism must begin, not *after* the birth of the child, but rather while it is still in the uterus.

The administration of iodine to all women in the endemic areas is feasible only by means of the introduction of the use of iodized salt by the governmental authorities, for women frequently are unaware of a pregnancy and, further, the indolence of the inhabitants would prevent their carrying out iodine treatment of their own accord.

The question as to whether cretinism can actually be prevented by such radical measures is, however, still uncertain and the answer may never be known with certainty, more particularly because cretinism, for reasons unknown, has shown a substantial decrease during several decades.

In all the *milder* cases of cretinism, the condition is usually recognized first when the child enters school, at which time the waddling gait, the deeply depressed root of the nose and the defective intelligence become apparent.

At this time it is too late for iodine treatment, and the dried and powdered whole thyroid gland should be administered (not thyroxin), thereby very excellent results are often attained

During the *school age* there very often appears an enlargement of the thyroid in children of otherwise healthy appearance. This goiter of school age gradually increases in size during the next few years. The goiter of school age is quite common in the endemic areas, as, for example, in Berne or in the Algau, up to 80 per cent of all school children being affected. Experience shows this goiter of school age to be a harmless phenomenon which is almost never associated with signs of hyperthyroidism. It usually regresses spontaneously at the completion of puberty and responds exceedingly well to small doses of iodine. Because of this fact we have entirely given up the operative treatment of the goiters of school age and if such goiters become troublesome, they are treated with small doses of iodine, which may be given to the children by the school teacher in the form of iodosterin tablets, once a week. At about the twentieth year this adolescent goiter very often disappears entirely. Occasionally it persists to some degree, in which case the response to iodine is not nearly so good as is that of the true goiter of school age. At about the twenty-fifth year of life there often develops a certain hyperthyroid symptom complex. If, in the female sex, a pregnancy should occur at about the twentieth year, it is common for a swelling of the thyroid (as well as of the pituitary, as is well known) to become apparent. These *goiters of pregnancy* ordinarily are not accompanied by signs of either hypo- or hyperthyroidism and they usually react very favorably to small doses of iodine. *After* delivery they slowly regress during the subsequent weeks in the majority of cases and during this period the young mother at times notices weakness with tremulousness, physical and mental excitability and general loss of strength. This *asthema of young women* often seems to be associated with the shrinking in size of the thyroid gland, together with some hyperthyroidism. In other cases the goiter of pregnancy persists and develops into a nodular goiter.

Since the goiter of school age, or adolescent goiter, is a harmless affair and responds brilliantly to iodine, the question arises as to whether iodine therapy is necessary at this age and whether it offers a dependable protection in later life. Is it possible for us to say that iodine therapy during school age gives us any prospect of a prophylactic effect against the later development of goiter or hyperthyroidism? I cannot answer this question in the affirmative. Indeed, I recall a number of cases where a youthful goiter was treated with good results and later during the thirties or forties a goiter appeared in spite of this fact, requiring operative interference. Further, we are unable to assert that the reduction of adolescent goiter to normal size and function constitutes a protection against the later appearance of Basedow's disease or of an iodine hyperthyroidism.

In the case of Basedow's disease, which I am unable to distinguish symptomatically from the so-called *Struma Basedowifcata* or iodine hyper-

thyroidism, pre-operative preparation with Lugol's solution in doses which are not too small, in the manner introduced by Plummer, has shown itself to be of such value that at the present time it has been introduced in practically all surgical clinics. On the other hand, *prolonged* treatment of Basedow's disease with small doses of iodine, as recommended by Neisser, is rejected by most physicians and considered dangerous.

I conclude. In those regions of endemic goiter, in the midst of which cretinism is observed with a good deal of frequency, and indeed only in these, prophylaxis by means of the administration of iodine to pregnant women should be instituted by the authorities. This is certainly possible only through the substitution of iodized or complete salt for the ordinary table salt. In all other endemic goiter areas, on the other hand, the obligatory introduction of iodized salt is not desirable. The general use of iodized salt may be conducive to harm, in the case of older people or, particularly, to goiterous members of the family. The goiter of school age and adolescent goiter promptly regress under iodine therapy and almost never demand surgical interference. It is as yet, however, not certain whether the iodine treatment of adolescent goiter affords prophylactic protection in later life against the occurrence of goiter and hyperthyroidism.

BLOODY PLEURAL FLUID, AN UNUSUAL COMPLICATION OF CIRRHOSIS OF THE LIVER¹

By HENRY A. CHRISTIAN, F A C P, *Boston, Massachusetts*

A NOTE on an unusual clinical picture is not inappropriate for a Festschrift to Joseph H. Pratt, who always has been an exponent of the art of being interested in the very unusual as well as the very common disease combinations of man. He is and always has been a keen clinician with an extraordinarily complete knowledge of medical bibliography.

An accumulation of pleural fluid in combination with cirrhosis of the liver appears to be not very unusual. Rolleston and McNee¹ quote Vedel and Puech as estimating it to occur in one-seventh to one-sixth of all cases, more often on the right than on the left side, often, according to them, as a manifestation of concomitant tuberculosis. However, a search through the Quarterly Cumulative Index back to its beginning in 1916 yielded only four titles (Salvatore,² Vedel and Puech,³ Clerici⁴ and Cassarini⁵) indicating papers on pleural fluid in association with cirrhosis of the liver. None of these were accessible to the author.

For the pleural fluid in patients with cirrhosis of the liver to be bloody in nature seems to be extremely unusual, since in this period no title could be found under either cirrhosis of the liver or various forms of pleural disease indicative of hemorrhagic fluid in the pleura in combination with cirrhosis of the liver. Rolleston and McNee speak of such hemorrhagic pleurisy as being of tuberculous origin, citing Barjon and Henry⁶ and Jean⁷ and reporting a case of their own, or as the result of alcoholism (Fernet⁸), or caused by trauma, citing a patient of theirs. The only case I have been able to find, independent of these factors, is one cited by them as reported by Taylor⁹. Examination of Taylor's report shows that a child of 13 with cirrhosis of the liver causing ascites, frequently tapped, developed near the end of life right-sided pain and a pleuritic rub with paracentesis the next day of nine pints of fluid. Two days later she died, and autopsy showed five ounces of blood-stained serum in the right pleural cavity, no evidences of pleural or pulmonary tuberculosis, normal heart and nodular cirrhosis of the liver. Taylor's title was "Cirrhosis of the Liver in Children, with Some Remarks on Cirrhosis", here there is nothing to indicate description of so unusual a complication of cirrhosis of the liver, very probably other cases may have been reported equally buried under non-committal titles.

Recently I have had opportunity to observe a case of cirrhosis of the

* Received for publication March 11, 1937

liver that, under observation, developed hemorrhagic pleural effusion requiring removal of paracentesis nine times before death

The following gives the important data about this patient. A man of 60 entered the Peter Bent Brigham Hospital on November 13, 1936, complaining of jaundice of five weeks' duration and of enlargement of the abdomen of two weeks' duration. He had a history of excess in alcohol intake, no history of syphilis. He had been obese, now weighing 260 pounds after having lost 100 pounds in two years by dieting. Jaundice was marked, with dark urine and light stools for 11 days, and then cleared up to recur two weeks before admission, when his abdomen began to increase in size. On admission he was jaundiced (icteric index 70), obese with enlarged abdomen, dull in flanks and showing a fluid wave. His heart was not enlarged, there was a loud blowing systolic murmur over the precordium. Liver and spleen could not be palpated. Urine showed bile, at times albumin and very occasional cells and casts in sediment. Phthalein excretion was 90 per cent in 2 hours and 10 minutes, blood urea nitrogen 12 mg per cent, plasma protein 5.7 gm per cent with globulin 2.5 per cent and albumin 2.9 per cent. Blood showed a moderate anemia (85 per cent hemoglobin, 3,900,000 red cells) and a normal leukocyte count (7,800).

On December 7 physical signs of left-sided pleural fluid developed, and, on December 10, 900 c c of bloody, bile stained fluid were withdrawn, which had a specific gravity of 1.008 and contained 23,000 red and 2,000 white cells per cu mm, 35 per cent lymphocytes and 65 per cent polynuclears. Tapping of left chest yielded bloody fluid as follows: December 15, 1,200 c c, 21, 800 c c, 28, 2,400 c c, January 7, 2,000 c c, 12, 2,000 c c, 23, 3,400 c c, 25, 1,600 c c, the red cells progressively rising to 600,000 per cu mm. On January 22 abdominal paracentesis yielded 3,100 c c of straw yellow fluid. As is so common in cirrhosis of the liver, from time to time fever developed, again to disappear. There was no apparent relation of the fever to the hemorrhagic pleural fluid. The patient grew progressively worse, and after five days of terminal fever died on February 6, 1937. Four roentgen-rays of chest, the first on November 20, when there was but a small amount of fluid in the left chest, never showed anything more than fluid and poorly aerated lung. Sediments from all nine specimens of pleural fluid were studied by methods of fixation and tissue stains, in the third, the pathological department made a diagnosis of tumor cells, no tumor cells were seen in the other eight.

The diagnosis in this case, particularly after the development of the hemorrhagic fluid in the left pleural cavity with its rapid reaccumulation, was actively discussed by the staff. At first the diagnosis of cirrhosis of the liver was held. With pulmonary and pleural signs appearing, it was thought that these resulted from a complicating inflammation. When the pleural fluid was found bloody and reaccumulated so rapidly, diagnosis veered to neoplasm, presumably primary in liver, as none could be demonstrated else-

where (negative roentgen-ray study of gastrointestinal tract, no evidence of prostatic tumor)

However, at a public clinic on February 4 the author of this paper expressed unequivocally his belief that the hemorrhagic pleural fluid was a result of the cirrhosis and was not of neoplastic origin and that the patient had cirrhosis of the liver of alcoholic etiology, in which possibly some lobules had undergone transformation into neoplasm

The patient died two days following this clinic and autopsy revealed the correctness of the above diagnosis. There was no evidence that neoplasm or tuberculosis was responsible for the recurring hemorrhagic pleural fluid. The gastro-esophageal venous system did not appear abnormally dilated

SUMMARY

A case is reported of cirrhosis of the liver with recurrent left-sided bloody pleural fluid, the pleural condition not the result of neoplasm or tuberculosis

- III Summary and conclusions

I INTRODUCTION

THE more heart disease there is, and especially the more widespread the publicity about it, the more important becomes the problem of cardiac neurosis. In fact it has assumed almost first place in our practice. Every week at least and sometimes daily for a while there are cases that must be carefully studied and treated with this point in mind.

The cardiac neurosis to which we refer is not neurocirculatory asthenia, which is not a mental and perhaps not even fundamentally a nervous state. We might better designate what we mean as *cardiac psychoneurosis*. It consists essentially of fear or apprehension about the heart, and it may be very severe and crippling. It is essential in the practice of medicine to recognize and to treat this condition early, for a long established cardiac neurosis may be almost incurable. The condition is increasing in frequency and is probably missed more often than any other cardiac diagnosis. It is time we laid the proper emphasis upon it.

Cardiac neurosis is always based on some very definite exciting factor. The occurrence of heart disease, especially heart deaths, among family and friends or even simply reported in the newspapers under dramatic headlines may initiate a cardiac neurosis in a person who is ready for a neurosis of some sort. The finding by a physician of a heart murmur, trivial or not, of some disturbance of rhythm which may be insignificant, of hypertension, great or slight, or of actual heart disease may be the exciting spark. A roentgen-ray report may unduly emphasize some unusual detail or an elec-

From the Cardiac Clinic and Laboratory of the Massachusetts General Hospital

trocardiogram may show an artefact or some slight deviation from the usual normal. Subjective sensations may be the starting point: a disagreeable extrasystole, a paroxysm of tachycardia, the manifold symptoms of neuro-circulatory asthenia, sighing respiration, true dyspnea, angina pectoris, the prolonged pain of coronary thrombosis, and the various pains in the center or left side of the chest of noncardiac origin (due to cardiospasm, bursitis, muscle strain, and pleurisy among others).

It is not always appreciated that the family or friends of an individual suspected of having some heart trouble may become more fearful than the subject himself and actually need more attention from the physician. Only recently we have had the interesting experience of being consulted by a woman 60 years old without evidence of organic heart disease, who had travelled from a distance for relief of frequent crippling attacks of paroxysmal tachycardia which had not been adequately controlled by any kind of therapeutic measure that had been tried. No doubt the specific therapy that we advised may be equally unsatisfactory but one thing we did do, and that was to uncover and to help clear up the main difficulty, which was not heart disease itself, nor the paroxysmal tachycardia, nor even the patient's cardiac neurosis, but a rather severe neurosis of fear in several members of a large devoted family. This was the crux of the situation and the abolition of that fear should make a great difference in the attitude of the family toward her illness. Likewise, it is not uncommon to encounter cardiac neuroses in young people with or without heart disease, that have resulted from over-solicitude of anxious parents.

The most difficult cases of all are those with serious heart disease complicated by cardiac neurosis. It is a common experience in practice that nervous prostration or a severe cardiac psychoneurosis following coronary thrombosis, especially in physicians, is more difficult to treat than is the myocardial infarction itself.

We shall present herewith a few selected and striking examples of cardiac neurosis, with and without heart disease, four in whom the cardiac neurosis was the outstanding condition and, in contrast, one, with autopsy, in whom very extensive heart disease was for a long time masked by a psychoneurotic state. We have recently presented in the *Medical Clinics of North America*¹ several other cases illustrating cardiac neurosis in its various forms.

II CASE HISTORIES OF PATIENTS WITH CARDIAC NEUROSIS, WITH AND WITHOUT HEART DISEASE

A Neurosis Predominating

Case 1 Neurosis Induced Largely by Neurocirculatory Asthenia Normal Heart

A young unmarried teacher, aged 37 years, was examined by us on September 15, 1936. He had had scarlet fever at the age of thirteen. His father, a physician, is alive at 70 years of age, nine years after the onset of angina pectoris and seven years after coronary thrombosis, his mother, aged 66 years, is of a nervous disposition, has hypertension, and complains of much palpitation of the heart.

As a boy the patient noted that he could not keep up with his playmates because of palpitation and breathlessness. Consequently he avoided strenuous exertion and had always avoided it since. About 15 years ago he began to have some aching to the left and below the left nipple usually following exertion or nervousness, and often associated with rapid forcible palpitation. In 1930 he was seen briefly by one of us (who was caring for his father at the time) and found to have a normal heart and a blood pressure of 110 mm mercury systolic and 70 diastolic. One month later, in September 1930, following unusual strain at his work, a period of nervous exhaustion and collapse occurred, associated with rapid palpitation (pulse rate 125 to 130). He went to bed with this illness, made a good recovery, and by December 1930 he felt quite well.

During 1931 he was in good health and able to play 18 to 36 holes of golf without difficulty, but he constantly took good care of himself. In 1931 he began to smoke cigarettes in gradually increasing numbers so that over a period of three years he was smoking as many as 30 a day. In February 1934 he began to find himself breathless on exertion (two flights of stairs) and to have palpitation and tachycardia as before. These symptoms, as well as some heartache, had continued unabated. During the year preceding his visit to us, he had taken on more strenuous work, had smoked heavily, and had found it necessary to give up golf and all other forms of exercise. The past summer had been particularly strenuous with teaching and lecturing and he had been under tension most of the time. With the aggravation of his former symptoms there had also been, on several occasions, pain in the left lower chest noted while riding over rough roads. He had also observed momentary "stopping of the heart" followed by a forcible beat. In July 1936 he began to have heartache and palpitation on retiring at night or on awaking during the night, particularly when lying on the left side. On July 10, 1936, he consulted a physician who told him that he had beginning angina pectoris and prescribed aminophyllin which was not taken. This diagnosis aggravated his symptoms further, increased his nervousness, and frightened him to such an extent that he resigned from the college where he was teaching and returned home on August 5, 1936. After a few weeks of rest at home he felt improved but he remained so worried over his condition that he insisted on being seen two weeks ahead of his scheduled appointment.

Careful questioning revealed no history of substernal pain. He was uncertain about radiation to the left arm and scapula, but frankly admitted that he had been looking for such radiation because he had heard one of us inquire about the characteristic radiation of the pain of angina pectoris in his father's case (coronary disease). He had also had access to medical books in which he had read about angina pectoris. Many physicians had assured him that his heart was normal, but the one who told him he had angina pectoris left the most profound impression. He was much depressed, wanted to know if he should claim disability benefits, and the inference was in talking to him that he had come home to die. He had taken bromides off and on for six years.

Physical examination revealed a heavy set man in apparent good health. The heart was normal in size, sounds, and rhythm. There were no murmurs. The pulse rate was 95. The blood pressure measured 132 mm mercury systolic and 85 diastolic. Except for slight acne over the back there were no abnormal physical findings. The fluoroscopic examination and electrocardiogram were normal.

He was told that his heart was normal and given complete reassurance on this point along with advice to avoid fatigue of nervous origin, to limit tobacco to three or four cigarettes a day, to take only small amounts of coffee, and to exercise regularly.

When seen again on October 2, 1936, he reported that he had been completely well in the past two weeks since being reassured about his heart, that he had walked

as much as 10 miles a day, and that the pulse had been slower and the heart action quieter than for years. Physical examination again showed no abnormalities. The pulse was regular at a rate of 84. The blood pressure measured 120 mm mercury systolic and 80 diastolic. He was reassured further regarding his heart and advised to continue as before.

In November 1936 it was necessary to reassure him once more of the unimportance of several vascular naevi that he had found on his skin after reading a medical reprint in which mention was made of spots on the skin in heart disease. In the latter part of December he reported a recurrence of many of his old symptoms in mild form attributed to increased nervous tension. By curbing his activities for several weeks these symptoms disappeared, and he is now in the good state of health which he enjoyed last fall.

Discussion The factors in the background of the neurosis in this case are obvious, and it would have been surprising if, under the circumstances, a neurosis had not developed. In the first place, we are dealing with a nervous, sensitive individual with longstanding symptoms of neurocirculatory asthenia who had always protected himself from physical fatigue. Secondly, his family environment was such that heart trouble was ever in his mind, his father having had coronary disease for years, and his nervous mother having hypertension and heart symptoms. Moreover, he had ready access to medical books and journals. In the third place, he had been working recently under much nervous tension. Fourthly, he was a heavy smoker and it is common for the excessive use of tobacco to render a person more heart-conscious. And finally, and most important of all, he was badly frightened by an apparently "snap" diagnosis of angina pectoris made by a physician who was not well acquainted with him.

In treatment this case illustrates the good result of complete reassurance about the heart and sympathetic advice concerning his condition and mode of life. In such a patient, for a while at least, repeated doses of reassurance are usually needed, but always a careful and complete examination is essential at the start.

Case 2 Neurosis Initiated by Paroxysmal Tachycardia Normal Heart

A 46 year old native housewife was first seen by us on February 17, 1936. Her family history was irrelevant. Her past history was unimportant except as it related to the present illness.

Fifteen years previously, about two months following the death of her only child, she was suddenly awakened one night by very rapid racing of the heart accompanied by severe pain in her left anterior chest. The pain was sharp and catching in character, was localized to an area about two centimeters in diameter over the fourth left costal cartilage, and was treated by the hypodermic injection of morphia. Following this, similar attacks of pain continued to occur at intervals of two to four weeks and were unrelated to exertion, emotional excitement, posture, meals, or respiration (except that during the pain she was unable to take a deep breath). The duration of the pain was from one minute to one hour, usually 15 to 30 minutes, and there was no radiation.

Relief usually followed the administration of morphia which had been given subcutaneously or by mouth for nearly every attack of pain. Nitroglycerine had

been tried but found ineffective. In December 1933 a brother, to whom she was much attached, died. Immediately thereafter her attacks of pain increased in frequency and severity so that she was confined to bed for 10 weeks. Since that time, over a period of about two years, she had had two to three attacks of "agonizing" pain daily, each requiring morphia ($\frac{1}{4}$ to $\frac{1}{2}$ gr) for relief. Also during this time occasionally she had a sensation of fullness in her throat and palpitation. These symptoms frightened her and were attended by breathlessness and flushing of the skin.

From April 1935 to January 1936 she was under the care of a physician who was able to bring about some improvement with reassurance, phenobarbital, quinine, and belladonna, and a reduction diet, but there were two marked exacerbations of symptoms in October 1935 and again in December 1935. It was at the latter time that she began to complain of oppression or constriction beneath the sternum, directly following the attacks of acute pain described above, and thought by the patient to have been relieved after 15 minutes by nitroglycerine. She complained now also of sharp discomfort in the region of the right scapula "like the pain of pleurisy" coming and going at times during the acute pain. Among other things she had been troubled by diarrhea for a "number of years." This had been aggravated by quinine, but cleared up following the administration of dilute hydrochloric acid.

Repeated examinations by competent men failed to reveal any significant abnormality of the heart or nervous system and after 15 years of symptoms her general health remained unimpaired. Although the consensus among those who saw her was that her symptoms were functional in origin and aggravated by addiction to morphine, it was also agreed that she should be studied with the possibility of paravertebral alcohol injection of the thoracic sympathetic ganglia as a means of relieving her paroxysms of pain. Accordingly she entered the hospital under the care of Dr J C White.

Physical examination on entry revealed a slightly obese woman, apparently well. The pulse was regular at a rate of 84. The blood pressure measured 118 mm mercury systolic and 94 diastolic. The heart was normal in size and sounds. There were no murmurs. The examination showed no abnormalities except for quite marked precordial tenderness on light palpation.

The urine, blood, and stools were normal. A lumbar puncture revealed normal dynamics and a normal spinal fluid. The spinal fluid Wassermann was negative. The Hinton reaction of the blood was negative. The basal metabolic rate was minus 3 per cent. The electrocardiogram was normal except for slight left axis deviation consistent with her build. Roentgen-ray examination of the heart and lungs and of the dorsal vertebrae revealed no abnormality. A Graham test for gall-bladder disease was negative.

While under observation, many of her attacks coincided with visits by the attending physicians. A typical severe attack as observed by one of us was as follows. At the onset, she grasped the area beneath her left breast with her left hand and rocked back and forth groaning with pain. Respirations became deep and rapid. From her breasts up the skin became deeply flushed, and there was some mottling in the flanks, but the lower extremities were not involved. The temperature and sweating of the extremities were normal, but she perspired a great deal over the face and chest from increased exertion. Breathing later became shallow but remained forceful and rapid. The pupils remained intermediate in position. While listening to the heart over a period of three minutes the rate varied from 100 while holding her breath to 180 while at the height of a fit of sobbing and moaning. However, there seemed to be no relation between the severity of the pain, as manifested by her reaction, and the rate of the heart. At times she complained just as bitterly when the rate was 120 as when it was 180. The rhythm was regular throughout.

The blood pressure at the height of the attack measured 200 mm mercury systolic and 100 diastolic. A $\frac{1}{4}$ grain dose of morphine quieted her within a few minutes and the pulse rate dropped to 100 with slight increases up to 120 as her sobbing and moaning gradually ceased. Forty-five minutes after the onset of the attack she was still holding her breast as if it ached but she was quiet and the pulse rate was 88. An electrocardiogram during the attack showed sinoauricular tachycardia, rate 130.

On February 19, 1936, Dr. J. C. White performed a left paravertebral novocaine block from the third to the sixth dorsal sympathetic ganglia, including the visceral rami, which gave good anesthesia over the area where she complained of pain. However, within $2\frac{1}{2}$ hours, as sensation returned, she had another severe attack of pain, proving that her pain was not visceral in origin, because, under these circumstances, pain is consistently relieved for 24 hours or longer. Two days later the area of painful sensation in her chest wall was injected with novocaine during an attack, but without relief of the pain. Having thus demonstrated the futility of any neurosurgical procedure for the relief of her pain psychiatric treatment was recommended.

On September 15, 1936, her physician reported that after several months of sanatorium care her morphine addiction had been broken and that her precordial pain had nearly disappeared. She was doing nicely with an occasional placebo.

Discussion This case is one of the utmost importance, for it represents a group of patients who have been unsatisfactorily diagnosed and handled. Her present illness dating back 15 years began apparently with a paroxysm of tachycardia attended by severe chest pain which awakened her one night shortly after the death of her only child. With this very first attack morphine was given and without careful analysis each succeeding attack was diagnosed as possible angina pectoris unrelieved except by morphine. In the first place it should have been quickly obvious that angina pectoris does not occur like this in a young woman and in the second place that angina pectoris does not require morphine. It is, of course, also important to note that nitroglycerine had been tried and found ineffective. A clue late in her disease was the exacerbation of her symptoms following the death of her brother to whom she was much attached.

It is quite probable, in fact certain, from our observations, that at least some and probably most of the so-called heart attacks were not of the nature either of paroxysmal tachycardia or angina pectoris. Early in her experience she had doubtless become sensitized by her original attack or attacks of paroxysmal tachycardia to any elevation of heart rate or increased force of heart action due to effort or excitement which would bring on a "heart attack" requiring morphine. The reaction in her case to any tachycardia might be considered a conditioned reflex. Repeated normal physical examinations and electrocardiograms made very unlikely a diagnosis of heart disease sufficiently serious to incapacitate her.

The most important factor of all in maintaining the prolonged psychoneurotic state was certainly the morphine therapy. She had become an addict. With morphine in the foreground, the background must always remain obscured no matter what the disease condition may be. The hysterical nature of the attacks with rapid relief by morphine bears witness to this.

Finally, the failure of the sympathetic and peripheral novocaine nerve block to relieve the attacks proves their hysterical foundation.

The cure of her morphine addiction has already resulted in improvement but emotionally she is still far from normal

Case 3 Neurosis Induced by Sudden Knowledge of Compensable Heart Disease while in Army Rheumatic Valvular Disease

A 29 year old native baker's helper who had not worked for 10 years on account of his health, was admitted to the Massachusetts General Hospital on March 14, 1936, complaining of attacks of precordial pain. He had had measles, mumps, and whooping cough in childhood, without significant complications. His appendix was removed in 1925 and the tonsils and adenoids were taken out in 1929. There was no history of rheumatic fever or chorea. He had smoked two packages of cigarettes daily until a short time before his entry to the hospital. One brother, a policeman, had been killed, another brother had died following the World War as a result of being gassed.

In 1926, while an enlisted man in the army, he had influenza, shortly following this illness he was declared completely disabled, because of heart trouble, by army physicians and given a medical discharge and a pension. One year later, in 1927, he began to have attacks of rather severe precordial pain, occurring once or twice a day, which he described as follows. The pain originated in the region of the apex of the heart, was dull, aching, and penetrating in character, radiated to the left shoulder and down the left arm to the hand, to the left chest posteriorly, and down the left leg to the knee. The attacks were of one to two hours' duration, were unrelated to effort, meals, or excitement, and were not relieved by nitroglycerine. Occasionally he was awakened at night by an attack of pain. In 1933, shortly after his government pension was entirely withdrawn, there was a sharp increase in the severity of his symptoms, which continued unabated coincident with his efforts to become reinstated on the pension list. In addition he began to notice moderate dyspnea, and rapid irregular palpitation on exertion, and with his attacks of pain. He had several severe nose bleeds in quick succession but no subsequent ones. For two years prior to admission he had had sudden syncopal attacks of unknown duration, occurring every three or four weeks, and followed for a short time by dizziness. He could suggest no precipitating factor for these attacks. For one year he had noticed slight pitting edema of the feet when he had been standing for an unusual length of time. For six weeks there had been fairly persistent nausea, he had vomited several times, and on three or four occasions he had suffered from severe frontal headaches lasting half a day. There was no orthopnea or cough.

Physical examination revealed a well developed and fairly well nourished young man with cyanotic lips. Breathing was normal. The heart was enlarged both to the right and to the left, the apex impulse lying in the midaxillary line, the right border of dullness $5\frac{1}{2}$ cm to the right of the midsternum in the fourth intercostal space. The heart action was forceful and the rhythm totally irregular. The rate was 80 at the apex and at the wrist. There were a Corrigan pulse and pistol-shot sounds over the peripheral arteries. At the apex there was a loud prolonged diastolic murmur, a loud slapping first sound, and a short blowing systolic murmur of moderate intensity. Fairly loud systolic and diastolic murmurs were heard at the aortic area and along the left sternal border. The aortic second sound was accentuated and greater than the pulmonic second sound. The blood pressure measured 140 to 120 mm mercury systolic and 60 to 50 diastolic. The lungs were clear. The liver edge was just palpable beneath the costal margin and slightly tender. There was no edema of the extremities.

The urine, blood, and stools were normal. The Hinton reaction was negative. A teleroentgenogram showed dilatation of the heart slightly to the left and markedly

to the right. Oblique views showed marked prominence of the left auricle posteriorly and some prominence of the left ventricle posteriorly. There was also marked enlargement of the right ventricle. The aorta was small, the pulmonary vessels were only slightly prominent.

These findings we interpreted as those of mitral stenosis and regurgitation combined with an aortic lesion (aortic stenosis and regurgitation). The electrocardiogram showed auricular fibrillation, ventricular rate 80, slightly widened QRS waves (early intraventricular block), a tendency to right axis deviation, and a normal chest lead.

The consensus among most of the observers who saw him had been that his pain was that of angina pectoris of the type sometimes seen in patients with rheumatic heart disease and extensive aortic regurgitation, notwithstanding the fact that the mitral valve involvement seemed preponderant in this case. He continued to have attacks of pain while in bed under observation and over a period of two weeks he was given morphia rather freely for relief. On account of the severity of his pain paravertebral alcohol injection of the upper left dorsal sympathetic ganglia seemed justified to some of the observers. This procedure was carried out with some difficulty on account of unusually wide and thick transverse processes of the vertebrae, but finally, after three attempts, the first to the fifth left dorsal ganglia were satisfactorily injected. The resulting anesthesia over the left chest and vasodilation of the left arm and hand indicated a sympathetic block, which, in the experience of Dr. J. C. White, had usually been adequate to relieve pain in cases of true angina pectoris. However, the attacks of pain continued as before and it then became evident that he did not have angina pectoris.

In reconstructing the case at the time of our first examination after the events recorded above it was apparent that he was having an extreme reaction to the precordial discomfort induced by a very large heart thumping against his chest wall. There were good reasons for considering psychoneurosis as the chief diagnosis superimposed upon a background of organic heart disease. He had received a pension from the government for years and when this was discontinued his trouble increased. His pain was atypical of true angina pectoris, originating mainly in the region of the cardiac apex where the heart displaces the ribs, radiating even to the left leg, lasting for hours, unrelieved by nitroglycerine, and often requiring morphia for relief. His heart did not show the marked aortic regurgitation which has been almost invariably present in cases of angina pectoris in young persons with valvular heart disease and finally, alcohol injection of the upper dorsal sympathetic ganglia on the left gave no relief. This opinion is further borne out by the fact that he has continued unimproved since his discharge from the hospital.

Discussion The neurosis in this patient was precipitated by the belated discovery of rheumatic heart disease when the patient was convalescing from a respiratory infection while in military service, and the importance of which was at once magnified by his immediate discharge from the service on pension. Any cardiac symptoms which this man had thereafter were naturally interpreted as serious.

The next step in his medical history was the marked exacerbation of his dolor pectoris following the withdrawal of his pension.

Then came the unfortunate label of angina pectoris to cripple him still more and, finally, to complete the picture there was the serious therapy consisting not only of morphine but also of the nerve injections. Confirmation of the diagnosis of psychoneurosis came with the failure of the nerve injections to give adequate relief.

Much time, money, and suffering could have been spared in this case by early recognition of the psychoneurosis and its proper treatment, chiefly by psychotherapy. It seems likely that even now the most effective measure would be the restoration of his pension. Such a thing as precordial rib resection might perhaps be advocated to give him subjective relief, but that is as yet an experimental measure.

Case 4 Neurosis Following Coronary Thrombosis

A 58 year old physician and naturalist was first seen by us on September 25, 1934, complaining of precordial oppression on effort. He had always had a "sensitive digestive tract" characterized by intestinal stasis and "auto-intoxication," but nevertheless he had been generally well and active. He had had pyelitis five years previously and severe whooping cough two years previously. He had used alcohol and tobacco heavily in years past, but both quite sparingly in recent months. He was overweight and had gained a few additional pounds recently. His father died of heart disease at the age of 46 years, his mother died of a "stroke" at 73 years of age.

For three and one-half years he had noticed on effort after meals an oppression in the left upper chest anteriorly radiating to the left shoulder and sometimes to the jaw, and relieved within a few minutes by resting. This symptom was somewhat worse after an attack of grippe nine months previously.

In May 1934 four months before his visit to us, he was awakened at 5:30 one morning by an attack of the chest oppression described above, which was, however, more severe than usual, lasting five hours and requiring morphine for relief. He had a slight fever for several days, the blood pressure fell to 85 systolic, and the white blood cell count on one occasion shortly after the onset of these symptoms was 18,000. He spent three weeks in bed and then gradually got up and about. On July 5, 1934, six weeks after the onset of the prolonged pain, the blood pressure measured 125 mm mercury systolic and 80 diastolic and a loud, late systolic murmur was heard at the cardiac apex by a consulting physician. The electrocardiogram at that time showed normal rhythm, rate 70, low voltage, late inversion of the T-waves in Leads II and III, and a normal Lead IV, altogether typical of myocardial infarction of the posterior or basal type. During his convalescence he had three or four brief attacks of chest oppression but none during the month preceding his visit to us. He felt well except for extreme nervousness and fearful apprehension about the consequences of his illness. He was afraid to be alone and insisted upon the constant presence and attentions of his wife. Because he had always led a fairly vigorous, physically active outdoor life, which he was now unable to do, his outlook was gloomy and he chose to look upon himself as entirely crippled and unable to carry on usefully.

Physical examination revealed a heavy set man in apparent good health, but somewhat nervous and apprehensive. The heart was normal in size, sounds, and rhythm. At the apex there was a slight late apical systolic murmur. The pulse rate was 80. The blood pressure measured 122 mm mercury systolic and 80 diastolic. The lungs, abdomen, and extremities were normal. Fluoroscopic examination showed the heart to be normal in size and shape and the lung fields clear. The electrocardiogram showed normal rhythm, rate 85, low voltage, and low upright T-waves in the conventional leads, a very definite improvement as compared to the original electrocardiogram in July 1934.

It was apparent that he had done well following his coronary thrombosis and that the basis of most of his existing symptoms was fear and apprehension. He was therefore strongly reassured regarding his heart, advised to resume some of his hunting and exploration but to avoid strenuous effort, to spend his winters in an

equable climate, and to carry nitroglycerine with him should the occasion arise for its use

He has been seen at intervals of six months since his first visit. During that time with much reassurance he has shown steady improvement and has been able to resume much of his former activity in his nature work outdoors. He still has some oppression in his chest on effort, particularly after meals or when nervous or fatigued, but he is able to get along quite well when he avoids exercise after meals and nervous tension. His physical, fluoroscopic, and electrocardiographic findings have remained much the same over a period of two and one half years. His mental attitude has improved greatly.

Discussion Little or no discussion is required in this case. One need only emphasize that coronary thrombosis, no matter how mild, is very commonly accompanied and followed by mental depression and fear especially in a physician. This tendency is likely to decrease rapidly in the future with the current discovery of many cases with small infarcts, long survival, and unhampered physical reserve. This case illustrates also the value of some other interest than the particular occupation of the individual, some interest which is not fatiguing and which may continue to be cultivated for years.

B Heart Disease Predominating

Case 5 Severe Coronary Heart Disease Masked by Psychoneurosis and Morphinism

A 34 year old manufacturer was seen by us on May 21, 1934. He had always led a strenuous life, smoked heavily, and had been under much nervous strain for years with family and community activities. He had had numerous illnesses and operations (appendix, tonsils, antrum, injured hands, and "adhesions"). In 1930 he began to take morphine for migraine and later it was necessary for him to take the cure at a sanatorium.

His father and mother died of heart trouble at the ages of 59 and 48 years respectively.

In July 1933 he strained himself holding back a car on a hill and was exhausted. He felt no pain then but on the following day his chest was lame in front and on the left side. Four days later he felt well and pitched hard in a ball game for seven innings, having to stop because of fatigue, and not because of pain. He was unable to play much golf for the next few days because of exhaustion. He then took a long train trip and two weeks after the ball game, while lifting his small son on the beach, he suddenly felt oppressive pain to the left of the upper sternum lasting five to ten minutes. This pain recurred at intervals throughout the day with increasing severity and duration until 9:30 p.m. when it became constant and required morphine, which gave him relief when given at 3 a.m. the following morning. An electrocardiogram taken several weeks after this episode showed definite evidence of myocardial infarction at the apex of the left ventricle.

After a prolonged convalescence with gradually increasing activity he returned to his former strenuous life about May 1, 1934. On resuming his usual activities he began to have sharp stabs of precordial pain several times daily at rest or on effort. When first seen by one of us he was under treatment for a renewed addiction to opiates.

On physical examination he appeared well but nervous and apprehensive. There was slight cardiac enlargement, confirmed by fluoroscopy. The heart sounds were

good, the rhythm regular except for an occasional premature beat, and there were no murmurs. The pulse rate was 90, the blood pressure measured 120 systolic and 75 diastolic. The electrocardiogram showed normal rhythm, rate 105, interrupted by one ventricular premature beat, flat T-waves in Lead I, and slight left axis deviation. A later electrocardiogram in September 1936 showed also an absent Q-wave in Lead IV, further confirmatory evidence of previous myocardial infarction.

It was the opinion of some of his medical observers that in spite of the definite evidence of coronary disease much of the precordial pain of which he complained was on a neurotic basis. After repeated medical investigations and prolonged rest without sufficient relief to allow him to carry on a comfortable and useful existence a diagnostic paravertebral novocaine injection of the upper dorsal sympathetic ganglia was done during one of his severe episodes of pain with almost complete relief within five minutes. He was so impressed with the relief obtained that he wished to have a resection of the sympathetic nerves no matter what the risk. This was attempted but he did not survive the operation. Postmortem examination disclosed extensive coronary sclerosis with old occlusion of the descending branch and thrombosis of the circumflex branch of the left coronary artery together with marked scarring of the left ventricle. There was a definite and pronounced aneurysmal dilatation of the anterior wall and apex of the left ventricle.

Discussion This case is of the greatest interest and importance and without its inclusion our paper would be open to serious objection. It presents the other side of the picture from that illustrated in the first four cases. With a renewed enthusiasm in the recognition and treatment of cardiac neurosis one may easily go too far and fail to recognize the presence of serious heart disease that may lead to early death.

This patient's coronary disease was in large part overlooked or minimized for several reasons, consisting of his youth, his obvious nervousness, his addiction to morphine, and his relatively normal physical examinations. The electrocardiogram, however, proved to be of vital importance as it has been in most of our other cases of coronary disease in youth. It showed, without question, the presence of extensive myocardial infarction which was later confirmed at autopsy.

The case illustrates, incidentally, the danger of radical neurosurgery, in the presence of severe coronary disease, in contrast to nerve injections.

III SUMMARY AND CONCLUSIONS

The growing importance of cardiac neurosis has impressed us with the need of its emphasis at the present day when there is so much publicity about heart disease. Every patient with cardiac symptoms or signs or with knowledge of heart disease in family or friends is a potential cardiac neurotic.

We have presented herewith five striking examples of cardiac neurosis. The first case had as a basis a hypersensitive nervous system, a history of heart disease in the family, access to medical literature, increased nervous tension in his work, and a hasty incorrect diagnosis of angina pectoris, the excessive use of tobacco may have been an aggravating factor. The second case was a young woman whose first heart attack, apparently consisting

of paroxysmal tachycardia with precordial distress, followed the death of her only child and was unfortunately treated with morphine, during the next 15 years she became a morphine addict and never showed any evidence of heart disease. The third case was a young soldier whose rheumatic heart disease was unfortunately discovered for the first time when he was suffering from neurocirculatory asthenia following influenza, and for which he was discharged as partially disabled from the army, an exacerbation of his symptoms followed some years later when his pension was discontinued and became so severe that it was confused with angina pectoris and treated with morphine and nerve injections. The fourth case is an illustration of the mental depression and neurotic apprehension which often follows coronary thrombosis, the patient was a middle-aged physician who made a striking gain after reassurance and the readjustment of his activities and interests.

It is obvious that the early recognition and proper treatment of cardiac neurosis by psychotherapy would have spared these four patients much time, money, and suffering. There are many other cases like these.

In contrast with these four cases we have presented one important example, case 5, of serious heart disease consisting of coronary thrombosis and myocardial infarction masked by psychoneurosis and morphinism in a young man whose electrocardiograms gave the necessary clues to the correct diagnosis.

AORTIC STENOSIS WITH SPECIAL REFERENCE TO ANGINA PECTORIS AND SYNCOPE [†]

By A W CONTRATTO, M D , and SAMUEL A LEVINE, M D , F A C P ,
Boston, Massachusetts

INTRODUCTION

THE accuracy of diagnosis, the interpretation of physical findings and the etiology, frequency and symptomatology of aortic stenosis have been matters of considerable controversy in recent years. About 30 years ago the diagnosis was often made on the basis of a systolic murmur over the aortic area without any other confirmatory evidence. It became particularly clear during the great war that this was entirely insufficient evidence to warrant the diagnosis, when in some army camps and in the hands of some boards that were examining recruits, large numbers of cases of aortic stenosis were being reported. Such cases were subsequently regarded as having neuro-circulatory asthenia, showing a basal systolic murmur frequently found in this condition. The result of this experience led to the view that still prevails in the minds of many, that aortic stenosis is rare. It will be clear from this study that the pendulum has swung much too far in this direction, and that many clinical aspects of aortic stenosis need reconsideration and reappraisal. Certainly it can be stated at the outset that aortic stenosis is a fairly common lesion, and that basal systolic murmurs cannot be dismissed lightly.

The purpose of this study is to review some of the clinical features of aortic stenosis that might help in diagnosis, and especially to discuss two complications to which attention has recently been called, i.e. the occurrence of syncope and angina pectoris.

Although there are numerous isolated references to aortic stenosis in the older literature briefly reviewed by Marvin ¹ and Margolies,² it is only in the last decade that the importance of this lesion has been stressed. Cabot ³ in 1926 reported 28 autopsied cases. He called attention to the greater frequency of aortic stenosis in the male sex, the absence of evidence of aortic regurgitation in approximately half of the cases, and the occurrence of the disease predominantly in individuals past 40 years of age. Willius ⁴ studied 96 cases, and stressed the fact that anginal pain was a common occurrence in 21 per cent of his cases. Forty-six per cent also gave a clear cut history of rheumatic fever. Margolies ² emphasized the frequency of calcification of the valve in aortic stenosis but regarded the process in the most part as

[†] Received for publication March 17, 1937.

From the medical clinic of the Peter Bent Brigham Hospital, Boston.

sclerotic in nature Christian⁵ reported 57 cases that came to autopsy, 21 of which had calcification of the aortic valve. He also predicted that the calcification could be visualized by the roentgen-ray. McGinn and White⁶ reviewed 123 cases of aortic stenosis that came to autopsy and 113 that were examined clinically. Only one-third of the cases that came to autopsy were accurately diagnosed during life. A definite history of rheumatic fever was obtained in 23 per cent of the autopsied group and 46 per cent of the clinical series. Faintness, dizziness or actual syncope were fairly common complaints, occurring in 22 per cent of the cases. Nineteen per cent had angina pectoris. Nine of the patients in their series died suddenly.

Marvin and Sullivan¹ reported 11 cases of aortic stenosis that died suddenly and presented the view that syncope and sudden death in cases of aortic stenosis may be due to a hypersensitive carotid sinus. Boas⁷ discussed 19 cases, four of which had angina pectoris, and believed that the angina pectoris was due to the narrowing of the aortic valve. LaPlace⁸ reported a series of cases of aortic valve disease and found that the degree of aortic regurgitation as measured by the diastolic pressure had no relationship to the presence of angina pectoris.

MATERIAL IN THIS STUDY

In the selection of material for this review only those cases were included that could be regarded as having definite evidence of aortic stenosis. The three main criteria were the presence of a systolic thrill at the base of the heart, the detection of calcification in the aortic valve on fluoroscopic examination and the postmortem findings. All cases that had definite evidence of organic involvement of the mitral valve were excluded in order to study the features of aortic stenosis per se, eliminating any complicating events that the presence of mitral valve disease might entail. For this purpose all the clinical and pathological data in the records of the Peter Bent Brigham Hospital, from the year 1913 to 1935 inclusive, were analyzed together with the cases seen by one of us in private consultation practice. This comprised a group of 180 definite cases of aortic stenosis.

ETIOLOGICAL CONSIDERATIONS

It has been and still is often difficult to establish a conclusive relationship between an early rheumatic infection and a subsequent valvular lesion. There is no indisputable and constant pathological finding which determines the rheumatic nature of any cardiac abnormality. The presence of Aschoff nodules in the heart, although very distinctive, is often wanting, even when there is every reason to believe that the lesion is rheumatic. An early rheumatic infection may have taken on one of the many bizarre forms so that the proper diagnosis never was made. Even when the correct diagnosis was made the patient and his family may not have been informed of it. When a great many years elapse, as often happens, before cardiac embarrassment develops, the early diagnosis may readily be forgotten. Finally

a positive past history of a rheumatic infection and the presence of a valve lesion is not necessarily proof that the former is the cause of the latter. One is therefore left with opinions rather than with proof.

If specific diseases from a clinical point of view are rarely if ever associated with the subsequent development of stenosis of the aortic valve, it is reasonable to eliminate them entirely from our discussion of causation. In this group may be included pneumonia, typhoid fever, syphilis, and many other specific infections. It may be mentioned at this point that we did not find a single instance in which aortic stenosis could have been due to syphilis, notwithstanding the great frequency with which this disease produces aortic insufficiency and aortitis. It is not certain, however, how often nonspecific infections of a mild degree such as the "common cold," influenza or sore throat were the etiological cause of cases included in this study.

The great frequency of calcification of the aortic cusps naturally led to the belief in the past that in many instances it was purely arteriosclerotic. This opinion seemed to be further validated, in many instances, by the absence of any previous history of rheumatism or of any other significant infections. In refutation one might offer the evidence that is found in the mitral valve. Here stenosis occurs and is frequently accompanied by marked calcification, even in comparatively young people in whom very few would deny the rheumatic etiology. This often occurs when there is no available history of previous rheumatism. In fact it is a common experience to find calcification developing in any old and prolonged inflammatory process like tuberculosis, syphilis, parasitic cysts and other conditions. From the above considerations it follows that a particular lesion of the heart may be regarded as rheumatic in origin if an early history of rheumatic fever, chorea, or other stigmata of rheumatic disease are present in a large percentage of the cases, and if there is no other predominating etiological cause. It is well to recall that in a large series of cases of mitral stenosis, which all regard as almost invariably due to rheumatism, a history of this early infection can only be obtained in slightly more than 50 per cent of the cases. If a similar incidence can be found in relation to any other valve lesion it is equally logical to assume that rheumatic fever is the etiological factor.

In this series of 180 cases there was a definite history of rheumatic fever or chorea in 57 instances (31.7 per cent). The figures for the two sexes were approximately the same. The interval between the first rheumatic infection and the time these patients were first examined averaged 23.3 years for the females and 28.9 years for the males. The extremes were quite wide, from a few years to 60 years. This is considerably longer than similar figures would be for cases of mitral stenosis. In addition there were 23 in which the history was questionable. By this is meant that there was a history of previous "rheumatism," sciatica, growing pains, nosebleeds, etc., or that a heart murmur developed after an early acute infection. If these are included the total incidence would be 44.4 per cent. This corresponds fairly closely to the observations of Willius⁴ who found a history

of rheumatic fever in 46 per cent of 96 cases of aortic stenosis. It is a somewhat lower figure than the 50 per cent that is generally found in cases of mitral stenosis. The difference in the two groups can readily be explained by the fact that aortic cases when detected are on the average 10 years older than those with mitral disease, the latter coming to a physician earlier in their course because of troublesome symptoms of congestive failure. The result is that the aortic cases have more frequently forgotten their early infections or these infections have occurred in an era when rheumatic fever was not so well understood.

From the above discussion it would seem logical to conclude that rheumatic fever is the most frequent and most important cause of aortic stenosis. Furthermore, we are of the opinion that arteriosclerosis and calcification are secondary manifestations superimposed on lesions due to rheumatic fever or to some other early nonspecific apparently mild infection.

AGE AND SEX

The age distribution in this group of 180 cases of pure aortic stenosis ranged from 13 to 81 years, with an average of 52.5 years. There were 108 males and 72 females, i.e. 60 per cent and 40 per cent respectively. The average age of the males was 53.6 years and of the females 51.4 years. There was no significant difference in the distribution of the two sexes in the various decades (figure 1) although the largest number occurred in

FIG. 1. Number of cases of aortic stenosis in various decades. ■ males, □ females.

the sixth decade. The incidence in the fifth and seventh decades was considerable. The number of females in this series was considerably greater than that reported by Margolies² or Willius,⁴ but more closely approximated that given by McGinn and White.⁶ The preponderance of males may possibly be explained by the greater frequency of chorea as the rheumatic manifestation in the female sex and by the fact that chorea rarely is responsible for subsequent aortic involvement.

BLOOD PRESSURE CONSIDERATIONS

The average blood pressure of 147 cases of aortic stenosis, in which readings were available, was 145 mm of mercury systolic and 84 mm diastolic. The range varied from a highest systolic reading of 260 mm and a highest diastolic of 156 mm, to a lowest systolic of 80 mm and a lowest diastolic of 10 mm. That hypertension was common is shown by the fact that there were 17 with systolic readings over 200 mm and 22 with a diastolic over 110 mm. The average pressures for the 85 males was 138 mm systolic and 79 mm diastolic, that of the 62 females was 153 mm systolic and 81 mm diastolic (figures 2 and 3). This tendency for the females to have a higher blood pressure is in accord with findings obtained in a comparative study of the two sexes in relation to other forms of heart disease, such as mitral stenosis or angina pectoris.

There are two factors in addition to the stenosis of the aortic valve, which have some bearing on the blood pressure level. Insofar as there might be an accompanying aortic insufficiency there will be a tendency for the systolic pressure to be somewhat elevated and the diastolic to be depressed. Such effects are commonly observed in pure aortic insufficiency. The other factor is the one generally called essential hypertension, or that associated with an aging process. This will tend to show higher pressure readings in the older group. The common occurrence of hypertension in many types of cardiac disease makes one suspect that the intrinsic lesions of the heart may in some reflex fashion be partly responsible for hypertension. Another possibility is that the original etiological factor, namely rheumatic infection, may not only have been the cause of the valvular lesion but also may have produced changes in the peripheral vessels which eventually led to hypertension. The study of individual cases of aortic stenosis gives one the impression that when no other mechanisms are involved the systolic pressure is likely to be low and the diastolic slightly elevated, resulting in a small pulse pressure. Notwithstanding this, all ranges of systolic and diastolic levels from very low to very high may occur.

PHYSICAL FINDINGS

Among the physical findings in cases of aortic stenosis there are some that are more peculiarly diagnostic of the anatomical lesion, and there are others less characteristic because of their common occurrence in a variety of other conditions. A systolic thrill in the aortic area, roentgen-ray evi-

FIG 2 Average blood pressure readings of cases of aortic stenosis (solid squares), as compared to normal individuals (circles) Male group

FIG 3 Average blood pressure readings of cases of aortic stenosis (solid squares), as compared to normal individuals (circles) Female group

dence of calcification of the aortic valve, a loud systolic murmur at the aortic area and a plateau pulse belong to the former group. Cardiac enlargement and an apical systolic murmur belong to the latter.

Cardiac hypertrophy is practically invariable in well marked aortic stenosis. In most cases this can be readily made out on physical examination, although during the early stages the percussion outlines do not always extend very much beyond normal limits. Marked dilation of the chambers such as occurs in mitral stenosis is not present as a rule, and therefore the cardiac silhouette is likely to be smaller, although the heart weight is greater in aortic stenosis than in mitral stenosis. In a previous study⁹ it was found that the average weight of the heart in cases of aortic stenosis was 669 grams while in cases of mitral stenosis it was 474 grams. The great difference is due to the marked hypertrophy of the left ventricle of the former. When the left border of dullness does not extend much beyond the nipple line the finding of a forceful apical impulse will often indicate that there is considerable hypertrophy of the left ventricle. This type of impulse, which lifts the finger slowly and remains lifted for an instant before it recedes, is quite unlike the short snapping impulse that is found in mitral stenosis.

An apical systolic murmur is a quite common finding but one that is difficult to appraise. It can be partly due to a transmission of a loud basal bruit, and to some extent it may result from an accompanying mitral insufficiency, either relative or structural in nature. Its presence or absence does not aid in establishing or eliminating the diagnosis of aortic stenosis.

The most constant physical finding is a loud basal systolic murmur best heard at the second right interspace, or over the midsternum. This murmur is often harsh in quality but we feel that its intensity is of greater importance than its quality. In fact one may say that faint murmurs are rarely harsh. When the loudness of murmurs was graded from I to VI¹⁰ as was done in many of the cases studied here, with rare exceptions the basal bruit was found to be of grade III intensity or louder. Often the apical murmur was just as loud as the basal and occasionally it was louder. There are other conditions in which loud systolic murmurs are heard at the base of the heart such as hypertension, congenital heart disease, anemia and hyperthyroidism. If these can be eliminated from consideration a loud aortic systolic murmur must always bring up the possibility of aortic stenosis. The direction of propagation of this murmur has been of no great aid in diagnosis. When loud it often could be heard throughout the chest, even in the right axilla. The importance of its transmission to the vessels of the neck has been exaggerated for this is due mainly to its intensity and to the proximity of its point of origin. There are occasional instances when the state of the circulation is so feeble that the murmur is quite faint and may only regain its loud and more characteristic intensity when the heart improves. It is in such cases particularly that roentgen-ray examination may be very valuable.

A blowing diastolic murmur heard in the second right interspace or along the left sternal border is a common, but by no means invariable finding in aortic stenosis. Stenosis of either the aortic or mitral valve frequently occurs without any auscultatory evidence of regurgitation. There are many instances of well marked mitral stenosis that show no systolic murmur whatever, and likewise many cases of aortic stenosis that have no diastolic murmur. In fact, of these 180 cases there were 87 in which no diastolic murmur was heard. To be sure this group excluded all cases with free aortic insufficiency, for this study was confined to well marked stenosis of the valve. In trying to elicit the aortic diastolic murmur, the fainter ones may be overlooked unless auscultation is carried out carefully, both in the recumbent and upright positions and during held expiration.

The most diagnostic physical finding is a systolic thrill. This is generally best felt at the aortic area but is occasionally present over the upper or midsternum and rarely to the left of the manubrium. A systolic impact must not be confused with a true thrill that has duration, for when the latter is really felt and congenital heart disease can be ruled out a diagnosis of aortic stenosis is almost certain. There will be very rare exceptions when a loud basal systolic murmur and a definite systolic thrill will be found and yet stenosis will be absent. The explanation of such findings is still obscure. The difficulty is that in less than one half of the cases will a thrill be palpable.

In only 21 of the 51 instances in this series that came to autopsy was a thrill found. Possibly in some, more careful palpation might have been more successful. In others terminal cardiac weakness may have been the cause of the absence of this sign. The thrill is often overlooked because palpation is not carried out or because when a thrill is faint it may be detectable only in certain positions. It may be necessary to have the patient sit up or lean forward or even hold a deep expiration while the base of the heart is palpated.

No careful analysis was made of the frequency of an absent aortic second sound, or the reliability of this sign in the diagnosis of aortic stenosis. We are certain, however, that in some of the cases a clear second sound was heard in the second right interspace, although in many it was either diminished or absent. In according importance to the character of the second sounds at the base one should remember that the sound heard over the aortic or the pulmonary area is not necessarily made by the corresponding valve. In some obvious cases of hypertension the second sound is louder over the pulmonary than over the aortic area, although aortic pressure is considerably higher than pulmonary pressure. Likewise in some cases of aortic stenosis a second sound heard to the right of the manubrium may be partly a transmission from the pulmonary snap. In general it may therefore be said that the aortic second sound in these cases occasionally is present, though generally diminished or absent.

A plateau form of peripheral pulse has long been regarded as a characteristic of aortic stenosis. The frequency with which this peculiarity of the pulse is observed is diminished by the difficulty of its recognition and also by the fact that its typical form is commonly altered in the presence of an accompanying aortic insufficiency or hypertension. However, there are instances in which careful attention to the quality of the radial pulse may supply valuable supportive evidence.

A peculiarity of the pulse less generally appreciated is that the rate not infrequently is slow. This was quite well known to the clinicians of former times for Fotheigill¹¹ in discussing aortic obstruction states, "the pulse is usually slow and steady." There are very few conditions apart from aortic stenosis in which the rate of the heart may be so slow in the presence of severe congestive heart failure, and where the slowing cannot be accounted for by a digitalis effect or heart block. This peculiarity on several occasions has been the first clue in reaching the correct diagnosis. The rhythm of the heart, unlike that observed in mitral stenosis, is generally regular. Of the 180 instances in this study auricular fibrillation was present in only 11 cases. Four of these were examined post mortem and none showed mitral stenosis. Factors such as age, sex, blood pressure and previous rheumatic infection were no different in the fibrillators than in those with regular rhythm.

ELECTROCARDIOGRAPHIC OBSERVATIONS

In 82 cases electrocardiographic studies were made. Our findings concerning conduction disturbances were similar to those recently reported.⁷ There were 14 instances of defective intraventricular conduction, including seven with typical bundle branch block. Three of the above 14 showed appreciable delay in the P-R interval and one had complete heart block. There were two additional cases of complete heart block. Conduction defects seemed to be more common in the cases of aortic stenosis that had angina pectoris than in those that did not have this complication. Eleven of the 82 cases had auricular fibrillation. Some of the others had extrasystoles of ventricular or nodal origin. It is significant that we did not have a single instance of right axis deviation in the entire series. If such a change in the electrical axis is found in aortic stenosis it should lead one to suspect an additional mitral stenosis. The main conclusion from the electrocardiographic studies is that defects in conduction are commonly associated with aortic stenosis.

ROENTGEN-RAY FINDINGS AND CALCIFICATION OF THE AORTIC VALVE

In the past there have been no distinctive roentgen-ray findings that characterized aortic stenosis. The boot shaped heart denoting a hypertrophied left ventricle, although common in aortic stenosis is also frequently present in pure aortic insufficiency and in some cases of hypertensive heart disease with left ventricular hypertrophy. Recently, however, the detection

of calcification in the aortic valve by fluoroscopic examination¹² has been of tremendous diagnostic value. This has invariably been indicative of a significant degree of stenosis of the valve. Inasmuch as this technic has been developed in the past several years, only 32 of the more recent cases of this series were fluoroscoped. Among these there were 26 instances in which this examination positively identified calcification of the aortic valve. Two of the remaining six were examined post mortem, one showed calcification, the other did not. It is evident that aortic stenosis may be present for a long period of time before calcification occurs in the leaflets. Such cases will necessarily be negative on fluoroscopy, and others may be missed because of the thickness of the chest wall or the faintness of the shadow. It also follows that calcification will be found more readily in the long standing cases. This is well borne out by the following figures. The average age of the group showing calcification was 60.3 years while that of the negative group was 42.6 years. The youngest of the positive cases was 45 years old, although younger individuals not included in this study have shown calcification of the valves by roentgen-ray. The value of roentgenographic examination is readily appreciated by the fact that in one half of the 26 cases, no aortic systolic thrill could be felt. In some of these the roentgen-ray was the only means of establishing the diagnosis. At present it may be stated that the roentgenological finding of calcification of the aortic valve is the most accurate single evidence of aortic stenosis, but that calcification may not be detectable during the early years of the production of this lesion.

THE OCCURRENCE OF ANGINA PECTORIS

Little mention was made in the older writings concerning the association of angina pectoris with aortic stenosis. Mackenzie¹³ stated that, "there may be symptoms of angina pectoris but these are due to associated changes in the heart muscle." Recently more attention has been paid to this relationship^{6, 7, 14}. The more recent teaching has been that although angina pectoris is commonly associated with aortic valvular disease it is due to insufficiency of the valve rather than to stenosis. The explanation that is offered for this association is that coronary flow takes place during diastole and that with the low diastolic pressure that accompanies aortic insufficiency there is inadequate flow through the coronary system with resultant relative myocardial anoxemia. This explanation is open to some doubt for there are those who believe that the main flow through the heart occurs during systole¹⁵. Apart from the theoretical controversy there are certain clinical experiences which make one doubt the accepted importance of aortic regurgitation in the production of anginal pain.

Free aortic insufficiency, syphilitic in origin, is rarely associated with angina except in those cases in which the coronary orifices are narrowed. Furthermore, as will be seen from the following data, angina occurs quite

commonly in aortic stenosis without any clinical evidence of insufficiency of the valve. The following explanation was kindly suggested to us by Dr Tinsley R. Harrison: "The two important points about angina and aortic stenosis seem to be (1) that there is no evidence of anything which can decrease the circulation to the heart in these cases and (2) that in such patients there is much less relationship of the pain to exercise than in ordinary coronary angina. As regards the first point, while in cases without aortic stenosis one almost always finds at autopsy either coronary arteriosclerosis, luetic narrowing of a coronary orifice, or a well marked aortic insufficiency with a low diastolic pressure during life (the latter producing angina by causing interference with the blood supply to the heart during diastole), in persons with aortic stenosis typical anginal seizures may occur in the absence of any of these factors, the aortic insufficiency either not being present at all or in many cases of such mild degree as to cause no lowering of the diastolic pressure. In such cases the pathological evidence does not point toward a diminution in coronary flow and the enlarged coronary arteries suggest that the flow during life was actually greater than normal. However, this does not mean that the mechanism of angina is any different in such cases from that occurring in other patients. The coronary flow has to be looked at not per se but from the standpoint of its relationship to the need for blood, the latter of course depends on the oxygen consumption of the heart, which in turn depends largely on the work done by the heart. The latter depends on three factors—the amount of blood expelled per unit of time, the pressure against which this blood is expelled, and the energy expended in imparting velocity to this blood. As regards the output of blood, the only case which we studied had a normal cardiac output. However, the pressure within the ventricle during systole is probably enormously increased and this of course tends to increase the cardiac work. Furthermore, while the velocity factor is, under certain conditions, a relatively small fraction of the cardiac work, it may become the greatest factor in aortic stenosis, where with a markedly narrowed orifice the rate of flow must be enormously greater during systole. It is possible and indeed quite likely that the velocity factor is more than 50 per cent of the cardiac work in a case of marked aortic stenosis. Therefore, even though the coronary flow increases, say three-fold, it is quite likely that the cardiac work may be increased four-fold, and this would of course tend to produce angina through the usual mechanism of myocardial anoxemia.

"As regards the second point, in the young patients with aortic stenosis we do not have pipe-stem coronaries but normal vessels which are capable of opening and closing. The attacks which come on at rest may very well be due to slight vasomotor changes in the caliber of the coronaries. Suppose that the arteries are wide open and are just able to transmit enough blood to prevent angina. Then even a very slight diminution in caliber could cause an attack. This is quite different from a normal person, where the arteries have large reserve and different from a person with extensive

coronary sclerosis where one can't imagine any opening and closing of the pipe-stem vessels "

Another explanation depends on the likeness of the aorta and coronary system to the common water faucet suction pump. The water flowing through the larger orifice causes a suction on the smaller orifice which enters it at right angles. The amount of suction is somewhat dependent upon the velocity of flow through the larger orifice. It seems reasonable to assume that in the normal heart with "paper thin" aortic valves, during systole these leaflets are fairly close to the coronary ostia preventing any such suction action. In cases of aortic stenosis with rigid, calcified immovable aortic valves, and markedly increased velocity of the blood flow, it is possible that this suction action may even draw blood out of the coronary arteries and lead to relative myocardial ischemia.

It was significant but by no means surprising that as many as 41 of the 180 cases, or 22.7 per cent had definite angina pectoris. (There were 28 additional questionable cases.) Of these 41 cases 22 were male and 19 were female, the average age of the former was 49 years (youngest 13 and oldest 64) and of the latter 59 years (youngest 25 and oldest 74). There was one case in the second decade, two in the third, three in the fourth, seven in the fifth, and the remaining 28 in the later decades. The average blood pressures for the two sexes in these cases were 136 mm systolic and 80 mm diastolic in the males, and 154 mm systolic and 85 mm diastolic in the females. These figures were similar to the blood pressure readings of the cases of aortic stenosis in general, but somewhat lower than those found in angina pectoris, unassociated with aortic stenosis.¹⁶ It follows that hypertension is not a factor in the causation of angina associated with aortic stenosis.

The frequent absence of aortic insufficiency in this group with angina pectoris is indicated by the fact that in 19 of the 41 instances, no diastolic murmur was heard. This signifies that not only is pure aortic stenosis a common occurrence but that a concomitant angina is frequently present without an accompanying regurgitation.

To further validate this point of view 31 consecutive cases of free aortic insufficiency were studied. Only four were found to have angina pectoris and they were all luetic. Very likely the coronary orifices were involved in these. The average age of the 31 cases was 41.6 years and nine of them were over 50 years of age. The blood pressure readings in this group were typical of free aortic insufficiency, the average readings being systolic 154 mm and diastolic 32 mm. In 15 instances a definite past history of rheumatic fever was obtained but the lesion had not progressed to detectable clinical aortic stenosis. The comparative rarity of angina in these cases of aortic insufficiency is in striking contrast to its frequency when the aortic valve is stenosed.

Inasmuch as the diagnosis of angina pectoris can only be made by a proper appraisal of the symptoms and because the subjective complaints that

lead to this diagnosis are often mild and may be over-shadowed by the more distressing breathlessness, the diagnosis is often overlooked. In many cases one has to initiate a direct inquiry into the possibility of any ill feeling in the chest on hurrying in the street, because the patient often will not spontaneously mention it. We feel that this type of careful questioning was responsible for the large number of cases of angina detected in this study. The importance of eliciting these symptoms lies in the fact that the frequency of angina throws some light on the prevalence of sudden unexpected death in aortic stenosis. Whenever the diagnosis of angina pectoris is correctly made one infers that that patient is subject to such a fatal outcome. It is interesting that of the 80 cases in which the type of death was known, nine dropped dead suddenly. In five of these nine cases a diagnosis of angina pectoris had already been made. We believe that in some of the others that died suddenly a diagnosis of angina pectoris could have been made if we had had the opportunity of inquiring carefully into the history.

One experience that we had bears directly on this point. A man of 50 entered the hospital complaining of increasing breathlessness. He showed the typical signs of aortic stenosis and marked congestive failure, and was studied most carefully by many physicians including ourselves. He improved on medical treatment and returned about one year later with recurrent failure. On this second admission a clear cut history was elicited by direct questioning of anginal distress, that antedated the first admission. It had been entirely overlooked by all members of the staff. After he had again recovered a fair degree of compensation and while feeling quite comfortable, he died instantly. If a proper history had not by chance been obtained he would have been classified in that vague group of cases of sudden death from aortic stenosis. Sudden death of this type can occur even in the very young who have aortic stenosis and angina pectoris, as was the case in a boy of 15 in whom both of these diagnoses were made, who dropped dead while going to school.

The duration of life in cases of aortic stenosis after the development of angina pectoris is not very different from what is found in ordinary angina. In the 19 patients of this present series who were known to have died, the duration of life after anginal pain first occurred was 3.3 years. Of 10 who were known to be still alive the duration was 5.5 years. The cases varied considerably and were too few in number to permit drawing any clear cut conclusions, but we have the general impression that the young rheumatic aortic case with anginal pain may carry on many years, although typical sudden fatality may occur at any time.

SYNCOPE

The occurrence of syncope in aortic stenosis was lost sight of until a few years ago. This was recently discussed by McGinn and White⁶ and in greater detail by Marvin and Sullivan¹. Knowledge of the rôle that the

carotid sinus may play in the production of syncope,¹⁷ naturally led to the suspicion that this same mechanism might account for the dizziness and fainting attacks that occur in aortic stenosis. With this in mind an investigation was carried out to test the irritability of the carotid sinus in some of these cases. In 19 a test for carotid sinus irritability was performed on each side and in none were positive results obtained for syncope, or dizziness was not produced*. Among these were two with a clear cut history of syncopal attacks. From this it seems unlikely that carotid sinus irritability can be a common occurrence in aortic stenosis or that it will explain, in the majority of cases, either the dizziness and fainting, or the sudden death. The possible rôle of the carotid sinus cannot be dismissed entirely, however, and further investigation is necessary. It is possible that reflex inhibition of the heart from a sensitive carotid sinus may be the cause of sudden death in rare instances. A more likely cause of sudden death is the same mechanism that prevails in ordinary angina. This assumption is particularly applicable in those cases in which the diagnosis of angina pectoris can be made. One may even postulate that some of the others die suddenly in their first attack of angina.

An attempt was made to detect clinical features which were characteristic of cases showing syncope or dizziness. There were 21 instances of true syncope and an additional 16 had significant dizziness without syncope. The average age of those with true syncope was five years greater among the males and 10 years greater among the females than the general averages. Despite their more advanced years those with syncope tended to have a somewhat lower blood pressure. Although these two differences were not great they may have some bearing on the production of the cerebral symptoms since both age and lower blood pressure may predispose to cerebral anoxemia.

TYPE OF DEATH

Ninety-five of 180 cases studied were known to have died. Of these 18 died of unknown cause, 44 died of congestive heart failure, 15 of subacute bacterial endocarditis, four of coronary thrombosis, two of cerebral accidents, two of pneumonia and one of Adams-Stokes disease. The remaining nine died suddenly and unexpectedly. There were some differences in age between these various groups. Although the average age at death of all the fatal cases was 51.3 years, the group with subacute bacterial endocarditis died at an average age of 36 years. Those that died suddenly had an average age of 45 years. The three most common types of death are congestive failure, subacute bacterial endocarditis and angina pectoris.

It is of some interest to analyze the duration of the more important subjective symptoms and objective findings in the group of fatal cases. Such an analysis gives one a guide as to the prognosis when particular

* Since this study was completed two cases of aortic stenosis were seen without any previous history of syncope or dizziness that showed definite positive reactions to carotid sinus stimulation.

features develop in the progress of the disease. Palpitation of the heart was an early complaint and the average duration of life after its onset was eight years. Dyspnea on the other hand came much later, as the average length of life after its first occurrence was only 23 months. The average period of survival after edema was 9.3 months and after appearance of syncope 9.1 months. Syncopal attacks that occurred early in life, 15 years or so before the patient was seen, were disregarded as they were considered to be unrelated to the disease. The duration of life after congestive râles were found in the lungs and definite pitting edema of the legs occurred was 6.3 and 4.3 months, respectively. In many of these cases the features just enumerated may have been present for some time before they were first noted, but in general it may be said that life expectancy is quite short once clear cut heart failure has developed.

DIAGNOSTIC CONSIDERATIONS

The more important diagnostic findings in aortic stenosis are a loud systolic murmur at the base of the heart, a basal systolic thrill, a plateau pulse and calcification of the aortic valve on fluoroscopic examination. The presence of a true thrill or calcification by roentgen-ray are quite reliable diagnostically. The other two features are not as trustworthy. This explains the difficulty in diagnosis and the fact that the majority of cases are overlooked. It is obvious that a fair degree of stenosis must exist for years before all the above criteria will be apparent. The early stages of the process must therefore be diagnosed on data that have been regarded in the past as inadequate. In a previous publication¹⁰ attention has been called to the importance of interpreting the presence of a systolic murmur as a possible early sign of aortic stenosis. In fact it was found that during the early stages a moderately loud systolic murmur that eventually proves to be due to aortic stenosis could be somewhat louder at the apex of the heart or the mid-precordium than in the aortic area. Also some cases regarded as having benign or insignificant systolic murmurs eventually prove to have aortic stenosis. With this in mind an analysis was made of 16 cases seen by one of us over the course of years, that eventually proved to have definite aortic stenosis but that had previously been misdiagnosed. Four of these were thought to have had mitral insufficiency, four aortic insufficiency, one a normal heart with a benign systolic murmur, six hypertensive heart disease and one chronic myocarditis. In none of these was a systolic thrill present at first, but in all either a systolic thrill or calcification of aortic valve or both developed. In conclusion it may be emphasized that loud basal systolic murmurs, especially in the absence of hypertension, must lead one to suspect the presence of aortic stenosis and make one search all the more diligently for other more convincing evidence.

POSTMORTEM FINDINGS

The main pathological finding that was investigated in this group of cases was the condition of the coronary arteries. The question naturally arises whether angina pectoris which accompanies aortic stenosis is due to atheromatous changes in the coronary arteries similar to those seen in patients without aortic stenosis or to the valvular lesion itself. The frequent occurrence of pathological changes in the coronary system in older people makes it necessary to appraise this problem in the younger group.

There were nine cases in this study with angina pectoris that were examined post mortem. Six were over and three were under 50 years of age. Two of the older group, aged 71 and 66, merely showed minimal changes in the coronary arteries without any narrowing of the vessels or infarction of the heart muscle. One case, aged 52, showed moderate sclerosis with narrowing of the coronary arteries and no myocardial infarction. Another, aged 66, had marked sclerosis and narrowing of the vessels with several small old infarctions. There was one, aged 62, that showed typical coronary thrombosis with infarction of the ventricle. The last one of this group, aged 52, had syphilitic aortitis, almost completely occluding both coronary orifices. Two of the younger cases, aged 46 and 25, had perfectly normal coronary arteries and the third, aged 46, showed moderate coronary changes without narrowing of the vessels. None of the last three had any old or recent infarctions of the ventricle. The complete absence of any alterations in the coronary system in two of the younger cases and the occurrence of only minimal alteration in some of the others, we consider as adequate proof that the anginal attacks were due to some other cause. It is more logical to regard this other factor as the actual valvular lesion. How this burden may be conducive to anginal attacks has previously been discussed.

Another pathological finding of interest is the localization of the calcification to the aortic valve and the ring. The deposits did not extend up to the mouth of the coronary vessels, which were distinctly free and open. In fact many cases of aortic stenosis, even in the older group, were comparatively free of atheromatous changes in the wall of the aorta itself.

SUMMARY

- 1 A study was made of 180 cases of aortic stenosis, unassociated with any other significant valve disease, 53 of which were examined post mortem.

- 2 Evidence was presented to indicate that the etiology in most instances was a previous rheumatic infection. It was thought that some early ill defined infections may have been the cause in a few cases.

- 3 It was found that although the male sex predominates, the ratio was not more than three to two. The largest number occurred in the sixth decade.

- 4 The average blood pressure of the males was 138 mm of mercury systolic and 79 mm diastolic, and for the females 153 mm systolic and

81 mm diastolic The range of these readings, however, varied from very low to very high systolic and diastolic levels

5 The most distinctive physical findings in aortic stenosis were a loud basal systolic murmur, a systolic thrill near the aortic area, and the detection of calcification of the valve on fluoroscopic examination In about one half of the cases no aortic diastolic murmur was audible

6 Disturbances in conduction such as bundle branch block and auriculo ventricular block were quite common

7 Twenty-six of 32 cases that were examined showed calcification of the valve fluoroscopically

8 Angina pectoris was found to be quite common, occurring in 22.7 per cent of the cases There is reason to believe that many cases are overlooked because of inadequate histories An explanation of the possible mechanism of angina in these cases, not dependent upon coronary sclerosis was suggested

9 There were 21 instances of syncope in this series In four of these and 15 other cases the sensitivity of the carotid sinus was tested and found normal It was found that sudden death occurred particularly in those with an anginal history, and that the carotid sinus was an unlikely cause of such eventuality

10 The three most common types of death were congestive heart failure, subacute bacterial endocarditis, and sudden death Once major symptoms developed in this group the average life expectancy was short

11 Although the finding of a basal systolic thrill or calcification on roentgen-ray examination are very reliable evidences of aortic stenosis, the diagnosis in many cases and especially during the early stages, will have to depend upon the intelligent appraisal of a moderately loud basal systolic murmur

12 A study of the postmortem material showed that the calcification is limited to the valve and does not involve the coronary orifices The finding of normal coronary vessels in two of the young patients who had angina, and the presence of only minimal atheroma in the vessels of some of the others that had angina strongly suggest that the deformity of the valve itself is in some way responsible for this complication

CHLOROSIS ¹

By ISADORE OTT ¹ M D, *Boston, Massachusetts*

CHLOROSIS is defined by Patek and Heath ¹ as "a hypochromic anemia in adolescent girls and young women, usually associated with gastrointestinal and menstrual disorders." According to many observers, Naegeli ² and Witts ³ among others, this condition, previously common, has become a disease largely of historical interest. Many of the younger clinicians who have not seen typical cases of classical adolescent chlorosis are inclined to doubt altogether the existence of this type of anemia. There is no doubt that chlorosis was quite frequent a quarter of a century ago. Its high incidence then, however, was more apparent than real. This is obvious from von Hoesslin's ⁴ critical analysis of 143 cases diagnosed as chlorosis. Of these 64 had histories suggesting tuberculosis, 25, gastric ulcer, 13, psychoneurosis, 13, secondary anemia due to endocarditis or other infections, and 5, excessive blood loss. The remaining 23 cases might have been called "possible chlorosis."

There are three factors responsible for the remarkable decrease in the frequency of this disease. The first is the introduction of more accurate diagnostic methods in the beginning of the twentieth century: the improvement in the chemical tests for occult blood in stools by Weber ⁵ who introduced the guaiac test, and by the Adels ⁶ who introduced the benzidine test, the discovery of the roentgen-ray by Conrad Roentgen in 1895, the introduction of accurate methods for hemoglobin determination by Gowers, ⁷ Veillon, ⁸ Tallquist, ⁹ Dare, ¹⁰ Haldane ¹¹ and Sahli ¹². Thus many cases previously diagnosed as chlorosis were discovered to have tuberculosis or some bleeding lesion in the gastrointestinal tract. A number of apparently pale patients were found to have normal hemoglobin values. The second factor is the improvement in the general and personal hygiene of the population. The third is the placing of many mild and some severe cases of chlorosis in the categories of nutritional anemias or microcytic anemia with achlorhydria.

Three cases of apparently classical adolescent chlorosis were seen by me recently. In view of the supposed rarity of this type of anemia the cases are presented here somewhat in detail.

* Received for publication March 4, 1937.

From the Medical Clinic of the Boston Dispensary, Service of Dr. Joseph H. Pratt, and the Department of Medicine, Tufts College Medical School. This study was aided by grants from the Charlton Research Fund, Tufts College Medical School and the Bingham Associates Fund.

CASL RLPORTS

Case 1 A girl, aged 19, was first seen in November 1936, complaining of weakness, some shortness of breath, palpitation and vague pains in the lower abdomen. She was born in Scotland and came to the United States at the age of two years. She was born at term and was of normal weight at birth. She received neither orange juice nor cod liver oil during early infancy. Her appetite has always been capricious and her diet grossly deficient in green vegetables and meats. At the age of five years she was told she was anemic and was given some medicine for the anemia, this she took for a short time. At the age of 10 years she was told again by a physician that she was anemic, this time she took the prescribed medicine for about one month. Her menses began at the age of 14 years, have always been very scanty, particularly during the past year.

There was no history of any previous serious illnesses or operations.

On examination the patient appeared well developed and plump. She had a temperature of 100° F (37.8° C) by mouth. The skin was strikingly white. The face was definitely puffy. The sclerae were not icteric. The mucous membranes of the mouth were very pale. The tongue appeared normal. The heart was normal except for a soft systolic murmur over the mitral area. Examination of the lungs, abdomen, pelvis and rectum was negative. The extremities were negative except for some pretibial pitting edema. The finger nails appeared rather thin.

The urine and stools were normal. Analysis of the fasting gastric contents revealed complete absence of free hydrochloric acid. After histamine injection the free hydrochloric acid rose to 10 units. The blood Hinton reaction was negative. The other initial laboratory findings are presented in table 1.

TABLE I
Initial Laboratory Findings in the Three Cases of Chlorosis

Case	Red blood cells per cu mm	Hemoglobin, per cent (Sahli)	Mean corpuscular volume of red cells, cu microns	Average diameter of red cells, microns	White blood cells per cu mm	Differential leukocyte count, per cent				Platelets per cu mm	Plasma proteins, grams per cent			Icteric index
						Polymorphonuclears	Lymphocytes	Monocytes	Eosinophiles		Total proteins	Albumin	Globulin	
1	4,920,000	52	67.0	7.21	10,750	69	16	11	4	2,671,000	5.6	3.1	2.5	5
2	4,440,000	55	—	6.66	7,500	58	35	5	2	499,000	4.7	2.7	2.0	5
3	4,160,000	50	—	6.74	6,300	55	37	6	2	1,467,000	6.3	3.1	3.2	5

The stained blood films of all three cases revealed small, pale red cells showing moderate anisocytosis and poikilocytosis.

This patient improved fairly rapidly under iron medication. The duration and quantity of her menses became more normal. The subsequent changes in the various blood constituents are presented in chart 1.

Case 2 A girl, aged 19 years, was first seen by Dr Frank Mirabello in November 1936. She complained then of a mild "head cold." She was born in Nova Scotia and had been in the United States for three years. She was born at term and had normal weight at birth. Her diet has always been adequate. Her menstruation began at the age of 13 years, and the quantity, duration and recurrence of the menses have been apparently normal.

CHART 1 The behavior of the red blood cell count, hemoglobin, mean corpuscular volume of the erythrocytes, average red cell diameter and plasma proteins in case 1 under iron therapy

On examination the patient appeared well developed, but rather thin. There was slight swelling and reddening of the mucous membranes of the nose and some generalized injection of the throat. The temperature was normal. There was moderate pallor of the mucous membranes of the mouth. The tongue was normal. The heart, lungs, abdomen and extremities were negative. The finger nails were normal.

The urine and stools were negative. Gastric analysis revealed complete absence of free hydrochloric acid after a caffeine test meal. The blood Hinton test was negative. The remaining initial laboratory findings are given in table 1.

This patient improved rapidly with iron medication. At the end of five weeks the red blood cell count was 5.33 millions per cubic millimeter, hemoglobin 82 per cent (Sahli).

Case 3 This patient is a twin sister of case 2. The history she presented is identical with that given by her sister. She was seen first by Dr. Mirabello in November 1936, complaining then of a mild acute upper respiratory infection. On examination the patient appeared well developed and well nourished. There was slight swelling of the nasal mucous membrane and slight reddening of the throat. The temperature was normal. There was moderate pallor of the mucous membranes of the mouth. The tongue was normal. The heart, lungs, abdomen and extremities were negative. The finger nails were normal.

The urine and stools were negative. Gastric analysis revealed post-histamine achlorhydria. The blood Hinton reaction was negative. The remaining initial laboratory findings are presented in table 1.

This patient improved rapidly under treatment with iron. At the end of five weeks her red blood cell count was 5.4 millions per cubic millimeter and the hemoglobin 74 per cent (Sahli).

The most significant deviations from the normal in patients with chlorosis are to be found in (1) the gastric secretions, (2) the blood plasma proteins, (3) the red cells, and (4) the blood platelets.

Gastric Secretions It is frequently stated that in chlorosis hyperacidity is common and achlorhydria rare. However, one of my patients revealed hypoacidity after the injection of histamine, another, achlorhydria after a caffeine test meal and the third, complete post-histamine achlorhydria. Of Patek and Heath's¹ four cases, one exhibited normal gastric secretion, two hypoacidity following histamine injection and one complete post-histamine achlorhydria. It would seem, therefore, that hypoacidity and even complete post-histamine achlorhydria are not rare in chlorosis.

Blood Plasma Proteins It has been pointed out (Naegeli,² Brugsch¹³) that in this disease the total plasma proteins may be reduced with the albumin-globulin ratio remaining normal. Two of my patients showed a reduction in the total plasma proteins. Decrease in the plasma proteins has been noted, however, in other types of anemia and has been observed also by Wintrobe¹⁴ in primary hypochromic anemia. When the reduction in the plasma proteins is considerable, edema may appear. However, the production of edema is not dependent solely upon the actual level of the plasma proteins (critical level is 5.5 ± 0.3 per cent, according to Moore and Van Slyke¹⁵), although this constitutes the most significant single factor. There are other factors, such as the total fluid intake and sodium chloride intake, which may play important rôles. It is perhaps for this reason that case 1 with a total plasma protein of 5.6 grams per cent exhibited edema, while case 2 with a total plasma protein of 4.7 grams showed no edema whatever.

Red Cells The total red cell count is frequently normal or even elevated above the normal level. The erythrocytes are small in size and poor in

hemoglobin and produce a hypochromic microcytic anemia of the type seen in conditions such as primary hypochromic anemia, nutritional anemia, chronic blood loss and hookworm disease (Wintrobe¹⁶), microcytic hypochromic anemia in infants and children (Faber et al¹⁷) and certain nutritional anemias in infants and children (Josephs¹⁸) The anatomy of the red cell in chlorosis is well illustrated by a diagram suggested by Haden¹⁹ showing a cross section view of the mean cell in various clinical conditions (figure 1)

Blood Platelets The most striking hematologic finding in patients with chlorosis is the frequently encountered thrombocytosis which may be very

FIG 1 Cross section and measurements of the erythrocytes in various clinical conditions

marked (table 1, chart 2) According to the method described by me elsewhere²⁰ the platelets may be divided, according to size, into four groups Group I, consisting of small platelets the diameter of which is one-quarter that of a red cell, or about 1.8 microns, group II, consisting of medium-sized platelets with a diameter one-third that of a red cell, or about 2.5 microns, group III, consisting of large-sized platelets with a diameter one-half that of a red cell or greater, or about 3.6 microns, and group IV, consisting of irregularly shaped platelets The differential platelet formula of normal adults is usually as follows Group I, about 19 per cent, group II, about 63 per cent, group III, about 17 per cent, and group IV, about 1 per cent The small platelets, those belonging to group I, are the juvenile forms and have been shown by Baita²¹ Zeller²² Jurgens and Naumann²³ and Jurgens²⁴ to agglutinate very readily The thrombocytosis in patients with chlorosis is characterized by the presence of numerous small platelets of group I These juvenile, easily agglutinating platelets constitute a significant predisposing factor in the development of spontaneous venous thrombosis at times observed in this condition (in 2 to 3 per cent of cases, according to Cabot²⁵) Chlorosis must be classed, therefore, as a definite thrombophilia along with conditions such as certain post-splenectomy states (Rosenthal²⁶), postoperative states (Hueck²⁷), fractures of long bones (Galloway²⁸), parturition (Dawbarn, Earlam and Evans²⁹), tuberculosis (Brock and Rake³⁰), malignancy (Naegeli³¹), polycythemia vera (Jurgens and Bach³¹), severe acute hemorrhage (Jagic and Klima³²) and post-infectious states In all these conditions the tendency to the development of spontaneous venous thrombosis is always associated with an elevated platelet count Essential thrombophilia recently described by Nygaard and Brown³ seems to constitute an exception, for in this condition the platelet count is normal The behavior of the total and differential platelet counts in chlorosis under iron therapy is totally different from the behavior of the thrombocytes in other types of anemia during treatment (chart 2)

There has been considerable diversity of opinion regarding the possible relationship between classical adolescent chlorosis, summarized recently by Patek and Heath,¹ and primary hypochromic anemia (called also idiopathic hypochromic anemia, simple achlorhydric anemia, cryptogenic achylic chloranemia, chronic chlorosis, hypochromic gastrogenous anemia) first clearly defined by Faber³⁴ and described more recently in detail by Witts,⁵ Dameshek,³⁶ Minot³⁷ and Wintrobe and Beebe³⁸ Thus Witts³ is of the opinion that, in the absence of achlorhydria and dysphagia, the microcytic hypochromic anemia in middle-aged women is allied to adolescent chlorosis Bloomfield³⁹ maintains that it is impossible to differentiate chlorosis from primary hypochromic anemia It seems to me, however, that chlorosis is a definite disease entity a view entertained by many observers, Minot³⁷ among others It occurs in two forms, a severe one which is rather infrequent and a mild one which is, according to Davidson,⁴⁰ quite common It presents a number of characteristic features differentiating it definitely from

primary hypochromic anemia, as shown in table 2. It must be admitted that atypical cases of both conditions are occasionally encountered which seem indistinguishable.

CHART 2 The behavior of the total and differential platelet counts in acute blood loss (venesection of 500 cc of blood on a normal adult who acted as donor for blood transfusion), chronic blood loss (chronic bleeding peptic ulcer), primary hypochromic anemia under iron therapy, pernicious anemia under liver therapy and chlorosis (case 1) under iron therapy. Dotted lines T represent the normal platelet levels, and dotted lines 1, 2 and 3, the normal absolute levels of the corresponding groups. Continuous lines T represent the behavior of the total platelet counts, and continuous lines 1, 2 and 3, that of the absolute counts of the corresponding groups.

SUMMARY AND CONCLUSIONS

Chlorosis, common a quarter of a century ago, has not disappeared. It is a definite clinical entity possessing characteristic features differing in

TABLE II
Differential Features Between Chlorosis and Primary Hypochromic Anemia

	Chlorosis	Primary Hypochromic Anemia
<i>Age</i>	14 to 20 years	Usually fourth decade
<i>Sex</i>	Limited to females	Usually in females, occurs rarely in males
<i>Symptoms</i>	Those of anemia	In addition to those of anemia, frequently sore tongue, dysphagia (Plummer-Vinson syndrome), paresthesias, diarrhea
<i>Skin</i>	Normal in appearance and texture, amount of pigmentation may be very scanty	Often dry, inelastic, may present abnormal pigmentation
<i>Hair</i>	Normal	Frequently dry, prematurely gray
<i>Finger Nails</i>	Usually normal	Frequently brittle, grooved or spooned
<i>Tongue</i>	Normal	Frequently atrophic
<i>Splenomegaly</i>	Rare (Naegeli ²), slight splenomegaly in 10% of cases (Castle and Minot ⁴¹)	Frequent (in 50% of cases (Witts ³⁵))
<i>Gastric Secretion</i>	Amount of free HCl may be increased, normal, reduced or absent	Frequently post-histamine achlorhydria (in 60% of cases (Wintrobe and Beebe ³⁸))
<i>Blood</i>	Leukocytes normal, often increased Platelets normal, frequently greatly increased	Normal, frequently reduced Usually reduced, occasionally normal (Dameshek ^{36 42})
<i>Bone Marrow</i>	Normal (Naegeli, ² Grawitz ⁴³) or hyperplastic (Lee and Minot ⁴⁴)	Always shows normoblastic hyperplasia (Kaznelson, Weiner and Reimann, ⁴⁵ Dameshek ⁴⁶)
<i>Thrombophilia</i>	In 2 to 3% of cases	None

many respects from primary hypochromic anemia. The most striking hematologic feature is the frequently encountered thrombocytosis which behaves in a characteristic manner under iron therapy. The thrombocytosis is characterized by the presence of numerous small, easily agglutinating platelets which create a condition predisposing to the development of spontaneous venous thrombosis and embolism.

THE LIFESPAN OF THE ERYTHROCYTES ¹

By LEOPOLD LICHTWITZ, M D , *New York, N Y*

IN anemia following bleeding or after the administration of phenylhydrazine, J H Pratt and P Morawitz in 1908 noted an increase in the resistance of the erythrocytes. During the stage of advance of the anemia and during the first period of the restitution of the red cells, the limits of the maximal and minimal fragility were shifted in such a manner that erythrocytes less fragile than normal appeared and the most fragile erythrocytes disappeared. Pratt, in collaboration with S Itami, continued these studies and found a considerable increase in the volume of the stroma of the erythrocytes during the phase of high resistance. This condition has been termed pachydermia of the erythrocytes by Morawitz.

In these studies Pratt touched the problem of the lifespan of the erythrocytes, our knowledge of which has not been advanced since. By counting the reticulocytes and analyzing the oxygen consumption of the erythrocytes, we can determine the presence of younger red cells in a manner approaching a quantitative measurement. By determining the osmotic fragility, which increases with age, we are able to get information on the age and the process of aging to which the erythrocytes are subjected. For this latter purpose we employ the method of L Chanel, J L Hamburger, and I Snapper which consists in determining the fragility by counting the number of erythrocytes undissolved in a series of concentrations of sodium sulphate solution.

In the organism, erythrocytes are destroyed by phagocytosis preceded by wear and tear, rather than by hemolysis. However, osmotic fragility indicates the aging process and can be taken as a quantitative measure, the units of which, namely, the concentrations, unfortunately cannot be related or transformed into units of time.

It is unknown whether the lifespan of the erythrocytes is shortened or lengthened in anemia. In the event that the lifespan of the erythrocytes is shortened, this shortening would contribute to the degree of the anemia, in the event that the lifespan is lengthened, this lengthening would compensate for the poor formation of the red cells.

In studying the osmotic fragility in anemic conditions, we rediscovered some findings made by Pratt and his co-workers. In anemia following hemorrhage, in pernicious anemia, and during the recovery period from these conditions, we found the least resistant groups of cells (i.e., oldest groups) absent, as indicated in the following protocols (tables 1, 2 and 3).

As shown in these illustrative examples, erythrocytes disappear before they approach the highest degree of osmotic fragility.

In anemia following hemorrhage there is no reason why destruction of erythrocytes should occur on a greater scale. From these observations it is evident that under the circumstances there is certainly no delay in the destruction of the erythrocytes and no prolongation of their existence. Therefore, it is reasonable to assume that the rate of destruction of the erythrocytes does not differ from the normal. Normally the daily production of erythrocytes equals the destruction (denominated as a), thus guaranteeing the constancy of their number. In any period of anemia in which restitution of the red count takes place, blood formation is increased up to about 100 per cent of the normal (i.e., to $2a$). If the average span of life of the erythrocytes is denominated as b , the whole number of the red cells is ab . Normally this figure is composed of groups of red cells equal in size but differing in age. When, by increased blood formation, the younger groups become larger ($2a$), the age groups are no longer equal. As blood destruction goes on at the same rate and each group is reduced equally by the hemorrhage, the oldest group is too small to cover the rate of destruction. Therefore, destruction must take place in the group next in age to the oldest.

group, and this process continues as long as the recently formed larger groups (2a) are aged down to the zone of destruction (table 4)

This may be demonstrated in the following table, in which, for the sake of better understanding, absolute figures are substituted for general figures and the age groups of erythrocytes reduced to 10

TABLE IV
Formation and Destruction of Erythrocytes after Hemorrhage in 5-Day Periods

[illegible]

Discussion of Table IV

1 Before hemorrhage, 5000 c c of blood are present The blood count is 5 million per c c The whole blood holds 25×10^{12} , and 1 liter contains 5×10^{12} erythrocytes

2 The erythrocytes are divided into 10 groups of different age Before the bleeding each group holds 0.5×10^{12} erythrocytes per liter and after the bleeding, 0.3×10^{12} The vertical columns show the composition of the blood in age groups during recovery The lifespan of the erythrocytes is assumed as 50 days

3 Normal formation and destruction of blood in 5 days $= 0.5 \times 10^{12}$

The erythrocytes formed during the recovery from anemia are aging, as shown in the table marked by the dark lines Thirty days after the hemorrhage, the blood contains 6 groups of red cells rather than 10 of different age, the older ones having disappeared After the thirtieth day, the recently formed erythrocytes enter the zone of destruction

As far as fragility is concerned, the findings in table 4 parallel the experimental findings demonstrated in table 3 While a restitution of the red blood count is finished within 20 days after hemorrhage, the restitution of the normal age groups of the red cells takes 70 days

The absence of the red cell groups made up of older erythrocytes in anemic conditions can be understood from the character and the action of the red cells

As the erythrocytes have no nuclei, no metabolism and no facilities for repair or for reproduction, they can hardly be considered as living cells Their main constituent, hemoglobin, performs its function of binding and releasing oxygen in the same manner when separated from the corpuscle, simply as a chemical compound The red cell is nothing more than a chemical machine and as such is subjected to wear and tear

The stress on the erythrocytes is evidently due to their function Binding and releasing oxygen is not only a chemical process, restricted to the quality of the hemoglobin, but concerns the red cell as a whole By taking up CO_2 from the tissues into the blood, chlorides and water enter the erythrocytes in order to maintain the osmotic as well as the acid-base equilibrium Thus the erythrocytes grow larger and assume a different shape The opposite process takes place in the lungs By this continuous process of hydration and dehydration, the stroma of the erythrocytes deteriorates The deterioration is noticeable by the decrease in the size of the erythrocytes and by their increased fragility

In anemic conditions a smaller amount of hemoglobin and a smaller number of erythrocytes have to carry the same amount of oxygen into the tissues Regardless of whether the release of oxygen in the capillaries, i e., the arterio-venous difference, is enlarged, or whether the erythrocytes are carried around more rapidly, the stress on the red cells is greater

The particular items are as follows 1 gm hemoglobin at 0° and 760 mm pressure binds 1.34 c.c. of oxygen (these figures are sufficient for comparison) Normally the blood contains 700 gm of hemoglobin Therefore, the arterial blood (350 gm of hemoglobin) is capable of binding about 500 c.c. of oxygen If the oxygen consumption in 24 hours is taken as 400 liters, and arterio-venous difference in oxygen saturation as 30 per cent, the erythrocytes have to act 2400 times in 24 hours in the double process of binding and releasing oxygen In anemic conditions this figure increases corresponding to the deficit of hemoglobin Thus erythrocytes are worn out faster With the number of actions, the stroma of the erythrocytes undergoes a continuous alteration, which after a definite number of these actions results in a state of inertia Every colloidal structure is subjected to this alteration, which, usually, is termed syneresis Erythrocytes with an outworn stroma are unfit for the process of hydration and dehydration, less permeable for gases as well as for water and ions, and ready for destruction even before they approach the highest degree of osmotic fragility

Thus it is evident that the lifespan of the erythrocytes cannot be measured in units of time, but only in number of actions The smaller the number of the erythrocytes, the larger the oxygen consumption, the shorter the lifespan of the red cells

The old and popular conception that by bodily exercise, outdoor life and high altitude blood is more rapidly renovated, is in complete harmony with these facts and their interpretation

THE MINNEAPOLIS GIANT ~

By H GRAY, *San Francisco, California*

GIANTS are not only dramatic to the layman as extreme variations of the human being, but valuable for the study of growth. In this respect they afford a considerable quantity of evidence which can profitably be analyzed in comparison with normal proportions, particularly of the extremities.

CASE REPORT

J A, a single white male of 46 years, may be called the Minneapolis Giant, after his birthplace. He was admitted to Lane Hospital November 1, 1936, with the chief complaint of foot ulcers of four years' duration.

Family History His father's father, the Norwegian Giant, was reputed to be 2520 mm in height (8 ft 4 in), while the father's own height was variously stated by the patient as 2286 mm (7 ft 6 in) and 1930 mm (6 ft 4 in), and the mother as 1880 mm (6 ft 2 in), there was one sister of normal size. The father died at 41 years of pneumonia, the mother at 32 also of pneumonia, the sister is alive.

Residential History Born in Minneapolis in 1890, he left there at two years for North Dakota, and at nine years started traveling in shows, all over the United States, and, according to his story, to Hawaii 14 times, to China several times, Australia twice, Europe twice, South America once. He has made Los Angeles and San Francisco his home for 13 years.

Occupation Carnivals, circuses, movies, shows, vaudeville, so many that he cannot remember the names of any except Harold Lloyd's "Why Worry?" in 1923, in the advertising for which he was claimed to be the second tallest man in the world. This claim would seem to indicate insufficient information about other living giants, which information, to be sure, is hard to get. For four years he has been unfit to work because of the ulcers on his feet.

Habits Very irregular. His sleep has been irregular and lately troubled with insomnia. Exercise has been minimal during the last four years because of the ulcers on his feet, so that he has spent most of his time sitting around. Drugs in any form are denied. Alcohol he drinks only occasionally and has never been an habitual drinker, though on October 30, 1936, he was arrested by eight policemen because he acted a little peculiarly, having consumed by his account "maybe five or six cases of whiskey." In jail his breakfast, according to the lieutenant, consisted of two gallons of coffee, and he admits being an inveterate coffee drinker, sometimes making it his entire meal and taking eight cups a day. Tea does not interest him. Also he is an habitual smoker. Lately he has been taking patent tonics to "build up his blood." His diet has been inadequate during the past four years.

Medical History Diseases, injuries, operations nothing significant. Questioned by systems, the points of possible interest may be reduced to the following.

Head No trauma, frontal headaches once a month during second period of growth at 28, for 15 years noticed that he had to turn his head in order to see toward the outer sides, and this bi-temporal hemianopsia kept creeping inward until about

* Received for publication March 20, 1937

From the Department of Medicine, Stanford University School of Medicine, San Francisco, California

five years ago both lateral halves of his fields of vision were almost gone, no progression since

Ears, nose, throat, lungs all negative Teeth all removed 8 years ago Hair on face and body always very scanty Heart slight dyspnea G I appetite always good but never Gargantuan Constipated for years G U Nocturia three times, for years, attributed to drinking a gallon of fluid a day Venereal denied No libido ever Muscular strength never remarkable Nervous system education

FIG 1 The Minneapolis giant, 2134 mm (7 ft 0 in) beside Dr J S M, 1763 mm (5 ft 9½ in net)

ceased at second year of high school, and subsequent learning has been difficult because of poor memory, especially of recent years His disposition he regards as nervous but good, except during 24 hours after attacks These will now be described

About five years ago, say in 1931, he had his first epileptic fit, he was very tired when he went to sleep and during his sleep he thinks he had an attack because when he woke up his tongue was sore His first attack in public was about four years ago when he was standing on a corner waiting for a street car, his body became stiff, teeth ground and he became unconscious for about five minutes, after which he felt

weak and slept for some time. The spells have occurred at intervals varying from two weeks to six months. The latest attack was two weeks before admission, he was sitting in a chair when he slumped over suddenly and fell to the floor unconscious, afterwards he was told that his legs had become rigid and then started quivering. His teeth grind and he thinks he bites his tongue. Never other injury. Never incontinent. He feels sleepy and depressed afterwards.

Olfactory hallucinations, an odor like hard-boiled eggs freshly opened, have been common since the grand mal began. Such uncinate attacks occur in 7 per cent of acromegalics (Davidoff¹).

Enlargement of hands, feet, jaw and lip he first noticed about 1921 at the age of 31, about five years after acromegaly was recognized at the Mayo Clinic. This extraordinary delay in a patient's appreciation of acral enlargement has previously been recorded by Buday and Jancso² (1894) and by Mark³ in his book on his own case.

Weakness began about the time of his second growth at 28, and has become worse in the last five years.

Ulcers began on his feet about 4 years ago. The first was on his right foot, apparently due to an inflammation under a callus, it cleared up. On his left foot the ulcer began about 18 months ago. He has been using crutches or a cane off and on for the last four years. Also there has been a fissure on his upper lip for the last five years, which has refused to heal, and which he attributes to repeated trauma from playing his harmonica.

Weight and Growth History This is shown in table 1.

TABLE I
Growth History

		{ 2134	7 0	122 0	268	
Nov 9, 1936	46 7			125 4	276	Gray

Physical Examination A veritable giant and obviously acromegalic. Mandible very long and large but protrudes only slightly. Maxillae very prominent as are the supra-orbital ridges. Lips thick. Voice is not deep nor loud but weak. Ears large.

Skin quite pale, somewhat tawny, is coarse but pliable with many wrinkles, it is loose and he has evidently lost weight

Eyes Pupils and movements normal without nystagmus, wears glasses

Fundi Generally pale Veins not especially full No sclerosis of vessels Both discs on medial halves are almost obliterated with irregular, poorly margined portion remaining Both discs in outer halves are pale yellow-white, more marked on left, appearance of optic atrophy

Ears Externally negative Watch heard, both sides, 25 cm vs normal 30

Nose Septum moderately deviated to right, no discharge

Teeth Out Oral mucous membranes moderately pale

Fig 2

Fig 2 Showing extraordinary claw toes and his characteristic posture and expression

Fig 3

Fig 3 Close-up of face and hand

Tongue Slightly large, no papillary atrophy

Tonsils, throat, neck, thyroid, heart, peripheral vessels, lungs, abdomen all negative

Pulse 54-84 Blood pressure 110 mm mercury systolic and 70 diastolic

Hair On scalp it is dark brown with some gray, fine in texture, normal in amount Brows and lashes normal On face only slight down, last shaved 5 months ago In axilla very thin and silky On chest none Crines scanty with horizontal upper edge On arms none On lower legs slight fuzz

Genitalia Penis small, about 5 cm long, infantile Testes small, soft, about 2 cm long

Rectal Sphincter tone poor, patient complains of great pain in rectum

Prostate Can hardly be felt

Spine No kyphosis, scoliosis, nor lordosis

Extremities Bony with wasted flabby soft parts Hands and feet large, only moderately large in proportion to rest of extremities Single penetrating ulcer on bottom left foot (J D Myers)

Urine Acid, 1010, no albumin, no sugar, no blood, casts or pus

Blood Wassermann negative, RBC 4 57 million, Hgb 70 per cent, WBC 11,100, neutrophils 68 per cent, eosinophils 5 per cent, basophils 1 per cent, lymphocytes 22 per cent, monocytes 4 per cent, and a few days later RBC 4 38, Hgb 68 per cent, WBC 12,350, neutrophils 68 per cent, eosinophils 1 per cent, basophils 0, lymphocytes 28 per cent, monocytes 3 per cent Sugar tolerance Fasting blood sugar 120, $\frac{1}{2}$ hr 160, 1 hr 165, 2 hrs 140 mg per 100 c c, cholesterol 117, urea 27, chlorides as NaCl 435 Van den Bergh direct negative, indirect 0 55 units, icterus index 4 3

Stool Negative

Basal Metabolic Rate Minus 17 per cent, pulse 60-58 Another day minus 11.

Electrocardiogram Sinus rhythm, rate 60, P R 0 17, QRS 0 08 sec, left axis deviation

Vital Capacity 61 liters

Shoes The heels on his shoes are 56 mm (2 2 in), and their weight is 3 2 kg (7 lbs)

Röntgen-Ray A film record was made of this gigantic skeleton The cranium is not enlarged, but its thickness is unusually great, the calvarium measuring nearly 2 cm in most places The jaws are edentulous, the mandible very long The sella is large, measuring about 2 cm backward, and is pretty deep, neither the floor nor the dorsum appear to be suffering from pressure atrophy, the anterior clinoids appear intact, although their structure is not very dense

In the infected left foot no roentgen evidence of osteomyelitis is detected, the right second and third metatarsals have been broken and the second is ununited with dorsal lateral displacement of the toe, this evidently happened a very long time ago

The phalangeal tufts of the big toes are quite unusual in form (figure 4) while in the other toes there is only a slight unevenness of the development of the tufts The tufting of the fingers is distinctly less than average (figure 5)

The heart is well within normal limits for a man of this size

The lungs show some infiltration in both upper lobes, on the right in the second interspace and on the left in the apex and first and second interspaces Also in the first and second interspaces are small areas which look like cavities but may be emphysematous blebs At any rate we have evidence of old tuberculosis in each upper lobe (R R Newell)

Eye Consultation O D 20/70, O S 20/25 Fundi discs markedly pale, vessels and maculae normal Fields bi-temporal hemianopsia, the field cut comes very close, up to about 2° to the macula on the right and to about 5° on the left (M Miller)

Orthopedic Consultation Clawing toes Marked prolapse of heads of metatarsals, especially left foot Chronic ulceration on sole without underlying osteomyelitis Some sensory disturbance Plates seem to be satisfactory Ulcer will probably heal with bedrest and elevation (D S King)

Neurological Consultation Tall individual with acromegalic features Generalized weakness but no paralysis No deep reflexes elicited No pathological reflexes All modalities of sensation intact except over feet and ankles where there is a marked hypesthesia and hypalgesia Muscle position sense in toes fair Cranial nerves Bi-temporal hemianopsia grossly Discs pale Balance of cranials intact Psychologically he is generally cooperative but quite easily irritated especially if obstructed in any way Manner effeminate and some of reactions quite juvenile and immature Sensorium intact I Q is 88 which is dull normal Some scatter shown indicative probably of organic deterioration Patient has expressed suicidal ideas which make

FIG 4 X-ray of foot of patient and of normal, which in this cut is raised to approximately equal magnification for clearer comparison of unusual bony structure

FIG 5 X-ray of hand of patient and of normal, showing relative size and absence of traditional tufting

prolonged hospitalization a consideration Impression 1 Pituitary adenoma with gigantism and acromegaly, destruction now resulting in hypofunction, 2 Epilepsy, symptomatic (J F Card)

Note by Visiting Physician (Nov 2, 1936) The patient is immensely tall, looks somewhat tired and worn and has clearly lost much weight Face has definite but moderate acromegalic appearance with thickening of supraorbital ridges and elongation of jaw Tongue is large Two plates Consistency of skin is thin and smooth There is transverse pubic hair of feminine type, moderate axillary hair, beard practically absent Considerable deposition of fat about hips Testes about 2 cm in length and infantile, penis not obviously abnormal Complete absence always of libido and potentia Heart is fairly large, slow, sounds clear Blood pressure rather low No viscera felt in abdomen There is definite bi-temporal hemianopsia with hand test There is definite grayness of optic discs on both sides Definite impairment of superficial sensation on feet Knee jerks not obtained in bed Definite deformity of feet which he thinks due to high heels Small penetrating ulcer on ball of left great toe, probably connected with this also Cranial nerves other than optic seem intact Impression The sequence of events here seems very clear 1 hyperfunction of alpha cells of anterior lobe, beginning early in life with simple gigantism There has probably been from the start a tumor which has destroyed or inhibited gonad-stimulating cells of pituitary, hence failure of sexual development, feminine habitus, lack of hair, etc 2 The tumor after a period of more or less arrest evidently began to grow again causing acromegaly and pressure on chiasm with optic atrophy and bi-temporal hemianopsia Secondary effects of long-standing acromegaly in form of weakness, anemia, etc, are explainable (A L Bloomfield)

Note on Epileptic Attacks on Ward (Nov 2, 1936) Yesterday afternoon at 4 30 the patient had an epileptic attack, he gave a cry, and was discovered in a generalized clonic convulsion, unconscious, with much grinding of the jaws Unconscious about five minutes, then lost abnormal movements, mentally confused for a few minutes, and fell into deep sleep This morning feels well except "washed out" (J D Myers) Similar attacks at 10 30 a m, Nov 11, 11 a m and 12 15 p m, Nov 13, 1936, but lasting only about half a minute

Diagnoses Giantism due to hereditary hyperpituitarism
 Acromegaly
 Hypopituitarism secondary to acidophile adenoma
 Hypogonadism
 Hypothyroidism
 Low I Q
 Epilepsy
 Uncinate attacks
 Anemia, secondary
 Ulcer of foot
 Claw toes
 Barbed-arrow phalanges
 Tuberculosis, inactive

Treatment The diet was made as ample as the patient would eat and was found to vary from 4000 to 5500 calories, an average day's distribution was C 410, P 140, F 320, calories 5080 Iron was given as ferric ammonium citrate 50 per cent solution, 4 cc t i d p c Liver and stomach concentrate was administered in the form of Extralin (Lilly & Co) capsules, each 0.5 gram, 2 t i d a c, which for the 24 hours is equivalent to 120 grams of fresh liver Adrenal cortex extract seemed indicated but before any was obtained the patient left the hospital on Nov 14 Thyroid extract (Armour & Co) 0.13 gram daily, was begun on Nov 7, and after four days the patient stated that his feet felt warm and sensitive for the first time in years

Limitation of the activity of the eosinophilic cells of the anterior pituitary by operation was proposed to Dr F L Reichert, but it was agreed to postpone surgical treatment until the general vigor could be improved. Radiation likewise was deferred, owing to the probability that the patient would leave town shortly so that follow-up would be inadequate.

After-History Jan 15, 1937, committed to Mendocino State Hospital

STUDY OF BUILD

Anatomical Measurements The build of this giant with acromegaly and hypogonadism (often called by the ambiguous term infantilism) may be documented by the following figures and tables. Although eager for relief the patient was, like most giants, resistant to tests in general and measurements in particular, after meals and gifts of tobacco he became slightly less suspicious, and after the ego had been elevated by lavish deference, could finally be coaxed into transient assent. Comparisons of his build with normals may conveniently be treated under four main headings, stature, general set of anthropological measurements, extremities, and miscellaneous measurements.

Stature Comparisons Humberd⁴ (1936) had "never been able to find an absolutely reliable account of a human being who has ever attained as much as 8 feet (244 cm) in height." Although he has tilted so persuasively at some reported data, as have others before him, there remain a number of undisputed taller giants (table 2).

TABLE II
The Taller Giants

Gallatin Giant	Lackey ⁵ 1899	2591 mm
Irish Giant in Trinity College, Dublin	Cunningham ⁶ 1891	2590 mm
Alton Giant Wadlow	Barr personal communication 1936, this suggests that he had developed some kyphosis when seen by Humberd in 1937 ⁷	2559 mm
Austrian Giant	Topinard ⁸ 1885	2550 mm
Giantess Wehde	Ranke, cited by Launois and Roy ⁹	2550 mm
St Petersburg Giant skeleton	Cushing ¹⁰ 1912	2540 mm
Kalmuck Giant in Orfila Museum, Paris	Topinard 1885	2530 mm
Alton Giant Wadlow	Humberd ⁷ 1937	2521 mm
Giant Byrne, or O'Brien	John Hunter, cited by Cunningham ⁶	2490 mm
Giant Wilkins	Dana ¹¹ 1893	2450 mm
Minneapolis Giant, the present case		2134 mm

General Anthropological Comparisons The giant's data are shown in table 3, columns 1 to 3. When we look for control series of measurements on tall, American born, normal, white men we find in no one place any set of dimensions complete. For the set used in our general routine study of build we chose the averages on the tallest group, namely 109 football

players whose average height was 1780 mm (70 1 inches) Since these appeared in a publication inaccessible in many medical libraries,¹² the essential averages and standard deviations are reprinted in columns 4 to 5 A coefficient is calculated in the next column, (6), by dividing the giant by the normal, for example, the coefficient for stature shows that the giant is 20 per cent above the normal Another method, more elaborate, but more refined, is to take the deviation of giant from the control and divide this by

the standard deviation (Dev /SD) as done in column 7, and to interpret this for the significant results, I have shown in column 8 how small a proportion of the population may be expected to show such extreme values, that is, if the distribution of giants follows the normal Gaussian law. Apparently it does not. Taking stature for an instance, the probability expected is seen to be 0 000,000,79, say, 0 000,001, hence in the United States with a population of over a hundred million people we should have more than 100 men as big as the Minneapolis giant, and certainly no such number has become known.

Extremities Comparisons Acromegaly In assessing the presence or absence of acromegaly, clinical practice might be made more objective by measurements aimed to determine whether the size of the organ, either absolutely, or better relatively to stature, is remarkable compared to that usual in normals. In the literature are scattered lengths and circumferences of such parts of the frame as happened to look extraordinary, usually without adducing control values from the literature or—when such do not exist, as is the case for many of the measurements taken—without supplying a single control. Clinical anatomy requires comparisons.

For the jaw, which it is true is hard to measure, the data are scantiest, and then by methods which are hard to apply in the living. By the method which is best to my mind, the radial distance from the earhole to the tip of the chin, what may be termed the chin radius or porion-menton, all that I can find are the following:

	mm	/S	Giant/Norm
Normal 1820 mm (71.7 in.)	128	7.03	
Minnesota Giant	155	7.26	1.21 = 21% excess
S.B. of Buday and Jancso ²	180	9.09	1.41 = 41% "
R.S. of Pentagna ¹³ 1932 (child 11 yrs.)	120	9.09	

Foot length will be treated briefly since (1) so much more material is available for the hand, and (2) our giant's foot, while of course large absolutely, is when referred to stature (FL/S) actually smaller than normal.

	mm	/S	Coef Giant/Norm
Minnesota Giant	306	14.3	1.17 absolutely
245 Old Americans of Hrdlicka ¹⁴ (1925) of average stature 1744 mm	261	15.0	95 relatively

Hand Size Methods have been exhaustively detailed by Bayer and Gray,^{15, 16} 1933 and 1936. In the present connection the most illuminating ideas are suggested by considering hand length referred to stature (100 HL/S). Since this relationship is smaller the taller the person, the ratio is plotted against stature in figure 6. Normal means (maltese crosses) for

increasing heights according to Bach¹⁷ have been spotted and a line fitted by eye to show the general trend. The variability of individuals is indicated by plotting 16 white males (simple crosses) (unpublished data). The Minnesota Giant is located (solid black spot). Other giants from the literature have been collected (open circles), these may be considered under several heads.

The extraordinary Alton Giant (double circles)⁷ is seen at three ages—12, 13, and 18 years. Clearly he was first a simple giant and later developed acromegaly.

FIG 6 Relative hand-length (HL/S) plotted against stature

A paradoxical group is next noticed: diagnosed giants and revealing ratios actually smaller than normal (small circles). Out of 45 giants there were 5 such, or 11 per cent. Incidentally the two juvenile giants bore the additional diagnosis of precocious puberty. Listing them in order of increasing stature we get table 4.

A group with such incredibly large values for this ratio HL/S that they would lie far above the nearest point on the diagram (therefore not inserted) are

		S	HL/S
R S	Pentagna 1932	1320	13.6
F V	Pel ¹⁸ 1906	1720	18.3

TABLE IV
Giants with Paradoxically Small Hands (HL/S)

		S	HL/S
K K, aged 8	Linsler ¹⁹ 1903	1380	10.9
C H, aged 6	Hudovernig and Popovits ²⁰ 1903	1400	10.4
Wurzburg Giant	Bassoe ²¹ 1922	1920	10.5
P C	Bonard ²² 1899	1940	10.1
American Giant	Hinsdale ²³ 1898	2286	10.9

The main group consists of persons diagnosed gigantism, acromegaly, or both (larger circles), then locations warrant the important conclusion that 89 per cent of giants are in fact acromegalic.

Hand Proportions in Detail A more refined comparison, partly as a

	PC/HL	99.6	114.4	.87
	Wr/HL	76.5	85.3	.90

matter of record, partly as a matter of method, can be given, based on 16 normal white males, for most of the measurements, though on only 7 of them for the items Bs, HC, PC, Wr. The principal conclusions are these. In absolute measurements the giant is over 30 per cent larger than the average for this particular sample of 16 normals. The measurements related to stature make allowance for the greater stature of our subject and are therefore more useful, they are given in the second panel of the table. They show that the giant's hand is larger relatively to his size than is the case with normals, with the exceptions that the circumferences of hand and wrist are smaller relative to height than is the case with normals. An acromegalic with the broad type of hand would perhaps yield circumferences relatively larger than normal. The measurements related to the size of the hand, as judged by the length of the central ray or hand length, is given in the third panel of the table, the index, ring, and little finger rays are all more nearly the length of the midfinger ray than is the case in normals, the thumb ray, however, is abnormally short. The data are in table 5.

Miscellaneous Comparisons. For the miscellaneous items put on record in table 6 satisfactory controls have not been found. In order not to extend

comparisons tediously, they may be ended with an examination of the relative growth of the three segments of the upper extremity—upper arm, lower arm, and hand length. In the present giant the overgrowth is least marked in proximal segment, next in the forearm, and most in the distal segment the hand. The analysis is given in table 7, in which as controls (column 4) I have copied the dimensions for the tallest group, stature 1920

TABLE VII
Relative Overgrowth of the Several Segments of the Arm

Segment (1)	Giant		Normal		
	mm (2)	% of Total (3)	mm (4)	% of Total (5)	Coef (6)
Upper	411	41.1	373	43.7	0.94
Lower	334	33.4	277	32.5	102.8
Hand	255	25.5	203	23.8	107.1
Total	1000	100.0	853	100.0	

mm, in Bach's table, then I have figured each segment as a percentage of the total extremity (columns 3 and 5), and finally divided the giant by the normal (last column), with striking emphasis stated, namely, the more distal the segment, the greater the degree of overgrowth.

ORGANIC DISEASE OBSCURED BY NEUROTIC BEHAVIOR^{*}

By MILTON C BORMAN, M S , M D , F A C P , *Milwaukee, Wisconsin*

THE frequency of neurotic behavior in patients seen in general medical practice, the difficulties met in making accurate diagnoses and in caring for such patients, the present interest of physicians and surgeons in this subject as shown by their writings and discussions, and the increasing number of patients labelled "neurotic," emphasize the importance of critical evaluation of emotional states in the sick

Symptoms of neurotic origin simulating true organic disease, but without demonstrable lesion, are common. Neurotic behavior, however, may follow or be intensified by organic disease, or such behavior may exist in the presence of organic lesions, in an apparently unrelated way. The patient is a total personality, and responds to intrinsic as well as extrinsic factors. It is therefore of great importance that we constantly remain aware of the possibility that symptoms may precede for months, even years, the discovery of a slowly developing organic lesion, screened and obscured effectively by neurotic behavior, as is demonstrated in the following reports

Case 1 An unmarried Jewess, 38 years old, complained of inability to walk. Fifteen years ago she had attacks during which she would scream, jump, stamp her feet, and become otherwise uncontrollable. She had always shown great pride, independence, jealousy, sensitiveness, explosive outbursts of temper, and a strong love of children. She had had an appendectomy, a right nephropexy, and a partial oophorectomy for dysmenorrhea.

For six years she had been under constant influence of self-administered sedatives because of sacral pain recently referred into the right posterior thigh unrelieved by tonsillectomy, hydrotherapy, heliotherapy, and psychotherapy including attempted hypnosis. She became lame nine months ago, falling several times.

Eight months ago there was flaccid paralysis of both lower legs. Vibratory sensation was impaired over the right tibia and ankle joint. Pain, touch, and temperature were denied completely over the sole of the right foot, and partially below the right knee. Laboratory findings were normal. The history of previous medication, an obvious toxic state, and complete reactions of degeneration below the right knee, warranted a provisional diagnosis of toxic neuritis at that time.

Five months ago an abortive right ankle clonus appeared. Four months ago the thigh muscles bilaterally showed increased tonus. Shooting pains in the lower lateral thighs, referred into the lumbar spine, became more severe, appeared oftener, and were associated with sudden intense contractures of the thighs on the hips. Occasional urinary and fecal incontinence developed. Three months ago right ankle clonus persisted. Continued spasticity in the thigh muscles appeared with paroxysmal spastic contractures, occurring every 10 to 15 minutes. The right knee jerk became increased. Sensory loss developed in the distribution of the twelfth dorsal, the lumbar, the first and second sacral spinal nerve segments. Another spinal puncture now revealed golden yellow fluid, strongly positive for globulin. A diagnosis was

^{*} Received for publication February 4, 1937.

From the Sacred Heart Sanitarium, Milwaukee, Wis.

made of extramedullary spinal cord tumor. Laminectomy revealed the tumor extending from the eighth to the twelfth thoracic vertebrae. It was successfully removed.

Since operation there has been improved sensation and use of the lower extremities. The patient's behavior, however, has remained typically neurotic. After the provisional diagnosis of toxic neuritis was made, eight months' continuous observation was necessary to establish a correct diagnosis. It had been necessary also to make repeated neurological examinations in order to sift out of a galaxy of bizarre symptoms and signs the above changes dependent upon the organic lesion.

Case 2 A housewife, 38 years old, complained of nausea, emesis, headache, diplopia, diffuse muscular soreness and aching pain in the left shoulder. For a year there were intermittent attacks of numbness and partial loss of strength in the left hand and forearm. For two months there had been intermittent weakness. She had become unconscious twice.

She had always been nervous. Nausea was felt when she heard unpleasant noises. She worried about a possible developing arthritis, uterine cancer, her husband's health, and financial losses. Eight years before she had collapsed following her husband's nervous breakdown. She had had yearly attacks of influenza since 1918. A four year old son, hyperactive and mischievous, caused constant anxiety. A year before she was in an automobile accident which produced great shock. Four months before she had had an acute attack of tonsillitis with subsequent tonsillectomy and post-operative hemorrhage requiring sutures.

The only positive physical finding was a transient bilateral squint which she said had been present since childhood.

After six weeks there was twitching of the muscles in the upper left face and intermittent occipital headache. A week later there was numbness in the left face, and rapid loss of power in both lower legs. She then recalled a similar, first attack which had occurred seven months ago. There was now a beginning neuroretinitis, and decreased sensation in the mandibular branch of the left fifth cranial nerve. She also recalled an attack of clonic contractures in the left upper arm with severe left cervical pain. The spinal fluid was under 56 mm mercury pressure. Other laboratory findings were normal.

A neurosurgeon found no definite evidence of an organic lesion, but requested that she return again in six weeks. Craniotomy then revealed "a very deep glioma of the parietal lobe."

Thus, we see that an emotional fog had successfully obscured the three cardinal features of a brain tumor.

Case 3 A Russian Jew, aged 49 years, complained of diffuse headache for two months, worse at night and when coughing. He had been a professional boxer, and drank alcohol to excess. He was much depressed, cried, worried about financial losses, and slept poorly. There was pain in the lower anterior chest, and for three weeks clotted blood was observed in his sputum. He had been told four months ago that he had heart trouble.

His pupils reacted sluggishly, incompletely and irregularly. His blood pressure was 160 systolic and 100 diastolic. The cardiac apex was palpable in the fifth interspace 2 cm. to the left of the left midclavicular line in the recumbent posture. Finger to finger test showed past pointing. Roentgenograms disclosed a dense shadow occupying the greater portion of the left lung field, appearing nodular under the fluoroscope. The heart, aorta and trachea were displaced to the left. The appearance suggested a new-growth.

Patient returned home for a week, developed a hemiparesis, and was taken to a clinic where bronchoscopic examination revealed a lesion involving the left main bronchus. The growth bled easily. It was clinically considered malignant, although a biopsy showed only inflammatory tissue. An intracranial metastatic growth was also considered to be present, and he died a few weeks later.

Business reverses suggested a cause for complaints in a patient, who for several years had sought escape from unpleasant facts in alcoholic sprees. Roentgen-rays of the chest and bronchoscopic findings finally established an organic basis for his illness.

Case 4 A married woman, 31 years old, began to complain two years ago of agonizing rectal pain aggravated intensely by defecation. Nine months ago she had recovered from influenza, and roentgenograms of her chest had shown enlarged hilar glands to which an elevation of temperature was attributed. She was finally taken to a neuropsychiatrist, who learned that her husband had been without a position for six months. Their mortgaged home might be lost. A nine year old son, with cerebral spastic diplegia, required constant care which could not be hired. Her husband's parents had little sympathy for their predicament. She had given up her study of music to which she had been devoted. Her husband accepted his parents' opinion even concerning routine household matters. She was sent away for treatment of her nervous state. She was in a hopeless, puzzled, depressed state of mind, her mental anguish probably worse than her exquisite, constant rectal pain. Examination showed a tender rectal mucosa exuding pyoid material. Complete relief of pain followed excision of a perirectal abscess and hemorrhoids.

Explanations to the patient and interviews with her husband directed toward increasing his understanding of her situation and the necessity of institutionalizing their child have enabled the patient to adjust herself to her situation and return home.

On physical examination, a perirectal abscess was found to have caused the pain which for two years was believed to be of neurotic origin.

SUMMARY

Neurotic behavior may mask organic disease so that it is unrecognized. In caring for the neurotic patient, it may be necessary sometimes to withhold judgment and examine the patient repeatedly in order to establish conclusively a correct diagnosis.

RELATION OF ERYTHEMA NODOSUM AND RHEUMATIC FEVER; A CRITICAL SURVEY

By HARRY KEIL, M D, *New York, N Y*

THE etiology of erythema nodosum has been a source of considerable controversy which has not abated, despite the acquisition of what is considered to be fresh and decisive knowledge on certain aspects of the subject. The point of view expressed will often depend on the nature of the branch of medicine practiced and the country from which the report emanates. Broadly envisaged, there are four principal schools of thought: (1) those who regard erythema nodosum as a specific independent entity, in this group are ranged the dermatologists (Tachau¹) and an occasional internist (Lendon's nodal fever²), (2) those who consider it to be chiefly, if not entirely, dependent on the factor of tuberculosis, in this category are to be found the pediatricians, (3) those who are of the belief that the eruption represents one of the rheumatic manifestations proper and, as a sub-class, those who are of the opinion that the skin lesions are of streptococcal origin, this group is composed preeminently of internists, (4) finally, there is an eclectic category of observers who consider erythema nodosum as attributable to a variety of causes, using as its chief argument the point that the rash has been encountered in the course of a host of maladies.

The principal purposes of this critical survey will be: (1) To discuss in some detail the alleged relation between erythema nodosum and rheumatic fever, a view which has numerous adherents today. While it cannot be denied that skin lesions of this type may be encountered under certain circumstances in the course of rheumatic fever, it appears that the data compiled in the past to substantiate this association are subject to much valid criticism. No attempt will be made to review the interesting streptococcal hypothesis, as the data which have come to light are too meager and inconclusive as yet. (2) To point out that the establishment of the diagnosis of erythema nodosum is by no means a simple procedure in all instances, and that the morphologic attributes of this eruption and of others simulating it are in want of further study and of critical analysis. Much of what has passed as erythema nodosum belongs, in reality, to another category of disease. It is apparent that in the pursuit of this problem the cooperation of the dermatologist with the other branches of medicine would be mutually profitable.

HISTORICAL ASPECTS

In the middle of the nineteenth century erythema nodosum was generally classed as "arthritic" or "rheumatic." In 1859 G. See³ concluded, on

* Received for publication March 20, 1937.
From Beth David Hospital, New York City.

the basis of clinical observation, that the joint pains encountered in this affection differed from those observed in rheumatic fever, that they represented a special type of arthralgia occurring before, during, or after the appearance of the eruption, that they were not characterized by redness of the overlying skin and swelling of, or serous effusion into, the affected joints, and, finally, that the articulations were capable of active and passive motion. It was also known at this time that the use of anti-rheumatic drugs was generally without avail. Trousseau⁴ was of the belief that erythema nodosum was a specific disease, separating it from rheumatic fever since, as he stated, "I have never seen redness or swelling in the situation of the affected parts, nor have I ever found signs of cardiac lesion." Bailow,⁵ on the basis of extensive observations in children, remarked that, "Erythema nodosum, it is well known, is associated with severe pains in the limbs and some fever and is sometimes followed, as rheumatism is, by considerable anemia. But I have never been able to assure myself of the production of an organic murmur in this disease, nor of any intercurrent arthritis, however slight, and it seems possible that the pains in the limbs may be accounted for, in great measure, by the effusions which, though limited in amount, often occur in spots which do not readily yield as on the front of the shins." Harrison⁶ pointed out that erythema nodosum does not, as a rule, recur whereas this is a striking characteristic of rheumatic fever. Garrod noted that "case after case presents itself in which the malady runs its course without implicating the heart, and this even in children who, as a class, show so great a liability to the cardiac accidents of rheumatism." West⁷ criticized the laxity with which the term rheumatic fever had been used in the past and he stated "This is especially true of erythema nodosum, which is still often called rheumatic because of the pains and fever, yet I have never seen erythema nodosum occur in the course of rheumatic fever, nor have I myself observed morbus cordis develop in the course of erythema nodosum, though I know such cases have been described."

Despite the doubts expressed by numerous able clinicians whose combined experience included observations in both children and adults, it is still currently accepted that erythema nodosum per se represents in part at least, one of the rheumatic manifestations. Perhaps the most famous exponent of this view was Stephen Mackenzie^{8a} who presented a paper (1886) based on a study of 108 cases of erythema nodosum. In 17 instances acute and subacute rheumatism were found associated. The criteria for the diagnosis of rheumatic fever rested on the occurrence of combinations of tonsillitis, fever, sour sweats, joint pains, and heart murmurs. However, close scrutiny of this report reveals that in many cases the only signs and symptoms, apart from the eruption itself, were joint pains and fever. Of the 17 instances cited textually, the thirteenth is of particular interest, as post-mortem examination was performed, the patient, a female of 18 years, had suffered from erythema nodosum in the first, second, and third attacks of "acute rheumatism," and finally was observed in the sixth recrudescence of

"rheumatism," accompanied by the eruption for the fourth time, yet necropsy examination disclosed no abnormalities of the heart. It is, of course, realized that this study could not, at that time, have embraced search for myocardial Aschoff bodies or of interstitial valvulitis, both of which may rarely occur in the absence of gross evidence of endocarditis. Nevertheless, it seems improbable that the patient had experienced six attacks of rheumatic fever in the sense in which that disease is understood today. Mackenzie included 17 additional cases of doubtful nature and, on the basis of his statistics, concluded that erythema nodosum per se is a rheumatic manifestation, even in the absence of other signs and symptoms. In 1896 Mackenzie^{8b} presented a comprehensive report based on the study of 125 more cases, which, together with his first group, totaled in all 233 patients. Of the combined series 43 or 19 per cent had suffered from what he called "undoubted articular rheumatism." An additional postmortem examination of a woman 47 years of age again revealed no abnormalities in the heart. These observations at necropsy tend to cast doubt, therefore, on the validity of the criteria used by Mackenzie for the diagnosis of active rheumatic disease. It seems curious that in reporting so large a series of cases, the factor of drug etiology as one of the possible causes of eruptions simulating erythema nodosum was not mentioned.

CLINICAL DATA

In the course of the following presentation, a number of statistical compilations will be cited. The figures are, however, not to be regarded in an arbitrary manner, as individual experiences vary greatly, it will be more instructive to take heed of the general principles involved.

1 *Tonsillitis* Erythema nodosum is accompanied by sore throat in a considerable proportion of cases, the latter being considered by Symes⁹ as the most common prodromal complaint. The average incidence of antecedent angina appears to be about 20 per cent (Bucher,¹⁰ 18 per cent, Hegler,¹¹ 20 per cent, Rolly,¹² 26 per cent). Hegler observed that the eruption succeeded sore throat after an interval of from three to seven days, others claim this period to be as long as 14 days or more (Symes), and it is possible that this symptom may be forgotten by the patient when the skin lesions make their initial appearance. Collis¹³ recorded an instance in which the dermatosis occurred after each of five separate attacks of tonsillitis. I have encountered several examples where this sequence of events was observed on two or more occasions. On the other hand, sore throat may first become manifest during the course of erythema nodosum or even subsequent to it. Skin lesions may also appear in the wake of other varieties of oral infection, such as alveolar periostitis (Arborelius¹⁴).

The incidence of sore throat will depend, in great measure, on the type of material studied. In a dispensary service, where milder instances of the disease are seen, tonsillitis is a prodromal complaint in only a small proportion of patients, roughly in about 15 per cent, when average care is exercised.

in taking a history. In patients with symptoms of sufficient severity to warrant hospitalization, the condition is more common, estimated at from 40 to 60 per cent.

Some observers believe that the occurrence of antecedent sore throat is evidence favoring the rheumatic etiology of the dermatosis. Such evidence per se does not, however, warrant this broad generalization, for it is known that tonsillitis may precede or accompany other affections having no particular relation to rheumatic fever. Moreover, the "rheumatic sore throat" appears to possess no pathognomonic clinical features by which it can be differentiated from ordinary angina. Gueissaz¹⁵ advanced the attractive hypothesis that the antecedent tonsillitis of erythema nodosum may pave the way for the rheumatic agent, but this theory is based on the supposition that joint involvement is necessarily synonymous with rheumatic fever. According to Hegler, there seems to be a parallel relation between the occurrence of sore throat and subsequent joint pains in erythema nodosum, but this association is by no means absolute.

2 Joint Involvement In many instances the diagnosis of rheumatic erythema nodosum has been postulated on the sole basis of articular pains, encountered commonly in the course of erythema nodosum (Hegler, 67 per cent, Mackenzie, 19 per cent). It is likely that articular pains are more frequent than is generally supposed, and that the figure arrived at will depend, to a great extent, on the type of material available for observation.

Patients seen in an ambulatory dispensary service only occasionally complain of articular disturbances. Frequently these are so mild that persistent interrogation is necessary to elicit this information. On the other hand, it may be difficult to distinguish these pains from the local discomfort produced by skin lesions, particularly when the latter are situated about the joints. Redness of skin overlying joint areas appears to be most commonly caused by cutaneous lesions, less frequently by peri-articular involvement, and rarely by intra-articular disease; it may be a clinical feat to determine with accuracy which of these factors is in operation. Fever may be minimal or absent throughout the short period of observation. Such patients are seen once or twice thereafter and then discharged as cured.

On the other hand, cases admitted to the wards of a hospital often present severe concomitant constitutional symptoms. Fever is generally found and may even attain a height of 105° F in exceptional instances. Progressive anemia may be noted occasionally. Usually the patient complains of moderately intense joint pains and while it is difficult to demonstrate definite intra-articular involvement, it is my impression that peri-articular disease was an occasional cause. In most instances the pains are of the nature of arthralgias. In the average case the symptoms are limited to the ankles and knees, but at times the joints of the upper limbs may be affected either simultaneously or subsequently, even in the absence of overlying skin lesions.

In the older literature the arthralgias encountered in erythema nodosum were designated as "rheumatoid" or "pseudo-rheumatic" for the purpose

of differentiating them from true rheumatic polyarthritis (See, Trousseau and others) Of 45 cases of erythema nodosum seen in adults, Hegler¹¹ noted rheumatoid pains in 21 patients (46.7 per cent) Comby,¹⁶ in a study of 172 children exhibiting these skin lesions, encountered 21 instances with joint pains (12.2 per cent), whereas Kuhn,¹⁷ also reporting on the disease in childhood, observed articular discomfort in but 2 out of 22 patients (9.1 per cent) There are many observers, particularly pediatricians, who deny the occurrence of joint manifestations in erythema nodosum Comparison of statistics indicates a higher incidence of "rheumatoid" pains in adults than in children H Koch¹⁸ has recently offered another interpretation of this phenomenon, claiming that there is no articular pain or swelling in association with erythema nodosum, but that the symptoms are produced by periosteal involvement, thus he was able to demonstrate microscopically in one case However, a single instance of periostitis, possibly the result of contiguous spread of the inflammation, does not warrant generalization

The association of "undoubted articular rheumatism" with erythema nodosum was recorded by Mackenzie^{8b} in 43 out of 233 cases (19 per cent) and by Hegler in 20 per cent of 45 cases, these observers were concerned principally with adults In children Comby¹⁶ reported but two instances (1.2 per cent) in a series of 172 examples of the skin disorder Comparison of statistics again reveals a higher incidence of joint involvement in the older age-group The term "undoubted articular rheumatism," when defined precisely, referred to swelling of the articulations, a manifestation considered to indicate true rheumatic articular disease in every case This view, therefore, requires qualification There are, however, occasional descriptions of erythema nodosum accompanied by articular disturbances closely simulating these regarded as characteristic, but not necessarily pathognomonic, of rheumatic fever Thus, cases have been recorded where there was migration of pains from one joint to another (Collis¹³), others in which the skin overlying the articulations was reddened, presumably from intra-articular disease (Patterson¹⁹), and still others in which the joints were exquisitely tender (Coburn²⁰) However, these phenomena are relatively uncommon Symes expressed the point succinctly when he stated that he had never observed in erythema nodosum the intense pain and fear of movement seen in acute articular rheumatism or gout, a statement with which my observations are in general accord I have encountered occasional instances, particularly in adults, where there was an indefinite systematic progression of joint involvement simulating migratory rheumatic polyarthritis At times pitting edema of the skin overlying articulations may be observed, especially in the vicinity of the ankles These cases could usually be differentiated from true rheumatic polyarthritis by the absence of effusion into joints, of characteristic flitting from one part to another, of exquisite tenderness and fear of movement, by the retained ability for active and passive motion when care was exercised, and by the general therapeutic inefficacy of salicylate therapy Broadly considered, these criteria apply in

the differential diagnosis from adult rheumatic fever, though it must be remembered that even in older persons, articular signs and symptoms may be just as atypical as in children. Nevertheless, it seems striking that erythema nodosum in adults rarely presents the features commonly encountered in typical rheumatic polyarthritides of the same age-group. In children, in whom articular symptoms are often atypical or lacking, other criteria must be invoked, particularly those concerned with evidence of cardiac involvement.

3 *Cardiac Disease* (a) *Endocarditis* Many authors (Hegler, MacKenzie, Kuhn, and Symes among others) have recorded the occurrence of transient systolic bruits at the apex or base of the heart in patients with erythema nodosum. Hegler, in particular, observed that occasionally the normal heart sounds may become impure, and that systolic murmurs may appear at the apex of the heart independently of the occurrence of articular pains. However, he recognized that genuine valvular defects, during or after the onset of erythema nodosum, "belonged to the rarities." Zuchholdt,²¹ an adherent of the view that endocarditis is an associated finding, made the significant statement that termination in mitral stenosis was rare. The auscultatory evidence of cardiac bruits, in association with joint pains and, perhaps also, antecedent sore throat has influenced clinicians to classify such cases as rheumatic fever, when the tuberculin test is negative, but this view often lacks substantial proof. The deceptive nature of functional murmurs as revealed by postmortem examination need only be mentioned. Undoubtedly the older literature abounds with instances where accidental bruits were considered as of organic origin. Symes stated that he had never seen cases with persistent systolic murmurs, these transient bruits were, in his opinion, either haemic in type or due to temporary dilatation of the heart. In many instances varying grades of anemia may develop, probably accounting for some of the functional murmurs heard. The minimum evidence required to deduce a relationship between erythema nodosum and rheumatic fever is the demonstration of organically diseased heart, occurring either simultaneously or subsequently. This statement is offered advisedly, as it is realized that the *clinical* evidence for the recognition of cardiac disease may not be apparent at the time of examination. When, however, postmortem study is available, it seems fair to insist on this criterion, the validity of which appears to be gaining ground (Fahr²² and others). No attempt will be made to describe the evidence of recent and old rheumatic involvement of the heart in its various forms, other than to state that there are ample criteria whereby the rheumatic nature of a case may be verified easily on microscopic examination (Gross). But the problem does not end with the demonstration of cardiac involvement, as will be shown in subsequent sections of this article.

From a clinical point of view, Gueissaz¹⁵ reported 300 examples of erythema nodosum in children and adults, with not a single instance of concurrent endocarditis. Gosse,²³ in a series of 100 carefully studied cases in

all age groups, was unable to find any example of endocarditis, and subsequent observation failed to disclose cases with mitral stenosis or other valvular defect. Kundratitz,²⁴ Pollak,²⁵ Feer,²⁶ and Kuhn¹⁷ among others were unable to discover a single instance of organically diseased valves in 81, 48, 45, and 22 children respectively with skin lesions of erythema nodosum. Of 86 cases of erythema nodosum observed in childhood, Ernberg²⁷ saw but one instance with valvular defect, but even in this isolated example he could not be certain of the relation. Comby, in 172 instances of the disorder in children, reported but two examples with coincident "acute articular rheumatism" and "mitral endocarditis," but he furnished no details relative to the precise nature of the valvular defect. Of 130 cases of erythema nodosum reported by Landau²⁸ in patients whose ages ranged from between 1 and 14 years, only once (0.8 per cent) was there an antecedent history of rheumatic infection, on the other hand, in 136 instances of rheumatic fever, Landau found a history of erythema nodosum in but four patients, an incidence which he regarded as no greater than that in other childhood disorders. I have observed many instances labeled as rheumatic erythema nodosum, owing to the occurrence of sore throat, joint pains, and a systolic bruit at the apex of the heart, but in no instance did the subsequent course disclose evidence of valvular defect, although some of the patients were followed for over five years. A distinction may be drawn between two types of cases: (1) where erythema nodosum occurs at the beginning of a febrile illness, (2) where erythema nodosum or lesions simulating it appear in a patient known to be afflicted with rheumatic heart disease. With regard to the first variety, the point should be stressed that such cases rarely, if ever, develop unequivocal evidence of rheumatic heart disease, when followed over a sufficient period of time. The recorded statistics on this phase of the subject, therefore, appear to be at variance with the view that rheumatic fever plays a major, or even a minor part, in the causation of this skin manifestation.

(b) Electrocardiographic observations have disclosed but few instances with significant abnormal changes. Master and Jaffe,²⁹ on the basis of daily electrocardiograms, concluded that "Cases of erythema nodosum revealed little evidence of myocardial damage and hence the relation to acute rheumatic fever is probably remote." Spink³⁰ observed that in 30 examples of erythema nodosum where serial studies of this type could be pursued, two cases showed evidence of prolongation of the P-R interval and one of myocardial disease. In evaluating data of this sort, it seems advisable to stress the points that (1) alterations in the electrocardiogram are not necessarily pathognomonic of rheumatic fever and are to be considered in terms of the entire clinical picture, as there are other diseases where similar changes may be encountered, (2) the criteria relative to prolongation of the P-R interval, particularly in border-line cases, vary with individual observers, this applies especially in the case of children, (3) the value of the fourth lead, as it concerns rheumatic fever, is still uncertain, this point is mentioned

as examples of erythema nodosum may be reported in the future with data bearing on this aspect of the subject, (4) finally, it remains to be noted that erythema nodosum or lesions resembling it may occur coincidentally in the course of undoubted rheumatic fever, this point will be elaborated upon in subsequent sections

(c) The simultaneous occurrence of pericarditis and erythema nodosum is extremely uncommon. In a survey of recent literature, Tachau¹ was unable to find a single instance of this combination. Coombs³¹ has stated that this association is not necessarily diagnostic of rheumatic fever, for, according to this observer, it may occur in erythema nodosum complicated by tuberculous pericarditis and miliary tuberculosis. Pericarditis may also appear as one of the manifestations of bacteremia accompanied by erythema nodosum-like lesions.

4 *Chorea* The association of chorea with erythema nodosum has been noted by a few observers (Garrod,³² Mackenzie, Bass,³³ Claman³⁴). Of 410 cases of chorea, Osler³⁵ found but one instance of this eruption or lesions resembling it. In a series of 100 cases of erythema nodosum, Gosse²³ encountered but a single instance of chorea, this he considered as indicating probable coincidence of diseases. The possibility of bromide or iodide erythema nodosum must be taken into account in cases of chorea where such medication may have been prescribed, as in a case observed by Bass³⁶. Considering the evidence at hand, the association of erythema nodosum with true chorea minor may be regarded as rare.

5 *Subcutaneous Nodules* The concomitant appearance of erythema nodosum and genuine rheumatic subcutaneous nodules is most uncommon. The association of the two manifestations has been reported by Weintraud,³⁷ Cheadle,³⁸ and, more recently, by Claman,³⁴ but it seems interesting to note that in at least the first two cases mentioned, the heart was not found to be involved. This appears curious when one considers the practically invariable occurrence of valvular disease with rheumatic subcutaneous nodules. I know of one example of this so-called combination of disorders, but in this case an erroneous interpretation of the phenomenon was offered, what was described as "rheumatic subcutaneous nodules" represented, in reality the remains of lesions of erythema nodosum which had implicated the panniculus adiposus without marked involvement of the superficial skin. Cognizance must be taken of the point that when the efflorescences of this skin malady are abortive in type or in the process of involution, they may lie subcutaneously, so far as the palpating finger can tell. The possibility of calling them "rheumatic subcutaneous nodules" is not remote, especially when one is influenced by the opinion that erythema nodosum is a rheumatic manifestation. The greatest care must be exercised in describing as rheumatic nodules those lesions occurring subcutaneously at the former sites of an eruption of erythema nodosum, as the latter may leave nodular infiltrations, without redness of the overlying skin, when the panniculus adiposus is involved to

a major extent This phenomenon appears to be more commonly encountered in the case of erythema nodosum of drug origin

6 *Pleurisy* With few exceptions (Wiborg³⁰ and others), implication of the pleurae has been uncommonly encountered in the course of erythema nodosum, except in the Scandinavian countries Of 30 cases of this skin disorder, Wiborg reported eight instances manifesting evidence of pleural involvement, of his entire series, 26 were patients whose ages ranged from between eight and 15 years This high incidence of pleurisy is nowhere duplicated or even approximated, except in reports emanating from Scandinavian countries where tuberculosis appears to be especially common Moreover, these cases have been cited as proof of their tuberculous etiology rather than that of rheumatic fever While symptoms of pleural involvement may occur in the course of rheumatic fever (pneumonia, pulmonary infarction, contiguous spread from pericarditis, hydrothorax, rheumatic pleurisy?), it seems doubtful that this isolated phenomenon can of itself establish the diagnosis of rheumatic disease There are observers who have never encountered this combination of disorders I have met with one such isolated instance exhibiting an unusually protracted course, but am unable to furnish information relative to the outcome In any event, it appears that pleurisy is a relatively uncommon phenomenon in the course of erythema nodosum, except in cases recorded from the Scandinavian countries

At this point it may be pertinent to mention the occurrence of a phenomenon that is foreign to the clinical picture of rheumatic fever, namely, the observation of hilar shadows in roentgen-ray pictures The presence of hilar glands has been variously estimated at from 50 to 90 per cent of cases of erythema nodosum affecting children I have seen several instances of this cutaneous malady in adults who likewise showed pronounced hilar shadows on roentgenologic examination, and it is likely that "hilitis" is more common in adults than has been suspected, this phenomenon being overlooked owing to its asymptomatic nature It is not my purpose to discuss the significance of this manifestation, except to state that its etiology is uncertain as yet Though the tuberculous nature of this phenomenon is accepted by most authorities, there are many lacunae in our knowledge of its nature

7 *Salicylate Therapy* On the basis of the alleged rheumatic etiology of erythema nodosum, salicylate therapy has been, and is still, used widely in this disorder It appears to be clinically established that the pyrexia and joint pains of rheumatic fever usually yield in a striking manner to these drugs, however, similar results may be seen occasionally in other forms of arthritis Gosse stated that salicylates have no influence on the essential course of erythema nodosum Lendon abandoned the use of the drug as it had little effect on the pains and fever curve of erythema nodosum and the experience of Symes appeared to be similar in this regard Whatever therapeutic results have been claimed for this form of therapy must be tempered by the knowledge that this skin disorder is generally of self-

limited course and of short duration On the other hand, Hegler recorded an instance in which large doses of salicylates were powerless to prevent the appearance of the eruption

8 *Activity in the Rheumatic Process* In order to determine the relation of an eruption to rheumatic fever, it appears advisable to lay down the following practical postulates (1) the disease process must be definitely one of rheumatic fever and the evidence must point towards activity in the disorder, to the latter part of this rule, there are some exceptions which will be discussed in another report, (2) the eruption must be related to the rheumatic process in such manner as to eliminate the possibility of coincidence of conditions Relative to the first point, I have observed two instances of erythema nodosum appearing in patients with inactive rheumatic heart disease of many years' duration Both were middle-aged women exhibiting signs and symptoms of mild congestive cardiac failure, subsequent observation failed to reveal clinical evidence of rheumatic activity In one case the eruption had recurred at intervals during the antecedent two years, no attempt was made to prove a probable drug etiology, although it was known that she had been taking potassium iodide during this period In the other case the dermatosis, morphologically resembling banal erythema nodosum in all particulars, was probably also caused by the intake of medication, as she had been using drugs to "relieve the nerves" It appears that the eruptions were in no wise related to the rheumatic process since in both instances, quite apart from their probable drug origin, they occurred in the absence of definite evidence of rheumatic activity Had these patients come to post-mortem examination, chronic valvular defects attributable to rheumatic disease would have been found in all probability, demonstrating the point that the observation of rheumatic heart disease post mortem in a patient previously afflicted with an eruption resembling erythema nodosum does not necessarily imply a relation between the two conditions

In addition, I have encountered several instances of erythema nodosum occurring in association with rheumatoid arthritis, non-gonorrheal in type These cases were characterized by the absence of evidence of rheumatic heart disease Such examples do not necessarily warrant the belief that rheumatoid arthritis and rheumatic fever are conditions related to one another or caused by the same etiologic factor

9 *Comparison with the Known Rheumatic Eruptions* Although ordinary erythema nodosum may be characterized by the appearance of a few successive crops of lesions and by subsequent relapses of the condition in occasional cases, it appears to differ clinically from the known rheumatic erythemas of the popular, marginated or flat circinate varieties (Keil) The latter exhibit clinical attributes that remind the observer of the essential characteristics of the rheumatic process They appear suddenly, their tenure of life is transient, lesions coming and going within a period of hours, occasionally one or more days, there is definite predilection for the trunk, they spread rapidly at their peripheries and have a marked tendency to form

configurations and bizarre shapes, there are usually many crops of lesions and, in occasional instances, they exemplify the chronicity of the rheumatic process by appearing at sporadic intervals over periods of months, and, rarely, even of years, there is generally associated undoubted evidence of heart disease, if not simultaneously, at least subsequently, and they are often accompanied by such rheumatic stigmata as transient subcutaneous nodules and chorea. The clinical course of an individual lesion is far more rapid and dynamic than in the case of erythema nodosum. On the other hand, the latter disorder, occurring at the inception of a febrile illness and being followed by undoubted evidence of cardiac involvement, is exceedingly uncommon.

10 Pathologic Features The absence of characteristic Aschoff bodies in erythema nodosum cannot of itself be used as an argument against its rheumatic origin, as this seems to be likewise true of the microscopic anatomy of the known rheumatic erythemas, concerning which, however, more study is necessary. Some observers are drawing etiologic conclusions on the basis of similarities in histologic alterations to the lesions described by Klinge.⁴¹ For example, Coburn⁴⁰ reported the case of a young woman who had erythema nodosum followed by polyarthritis. On the basis of the joint symptoms and the microscopic findings in sections of skin, he concluded that the eruption was of rheumatic origin. Histologic study disclosed vascular changes characterized by "swelling of endothelial cells which appeared frayed out into the lumen" and "escape of erythrocytes through the wall of the vessel, causing hemorrhage into the surrounding tissues. Throughout the connective tissue and fat, there were scattered foci of infiltration by polymorphonuclear leukocytes. There were also areas of swelling of the fixed tissue cells and an edematous appearance of the tissue itself. In one or two of these areas, multinucleated cells were seen." While swelling of the collagen bundles of the skin as well as vascular changes accompanied by intense edema of the pareties may present gross similarities to the type of lesion described by Klinge, it seems fair to note that such pathologic alterations have not been demonstrated beyond peradventure to be necessarily pathognomonic of rheumatic fever. The histologic description recorded by Coburn corresponds with that observed in banal erythema nodosum (Symes), even to the presence of giant cells which apparently represent a reaction to foreign bodies (particularly fat products) formed in the panniculus adiposus. Similar pathologic alterations may be encountered in cases of erythema nodosum where there is no definite evidence of rheumatic fever. This is one instance where clinical study seems to yield data of greater importance than that furnished by the pathologic approach.

CONSIDERATIONS ON THE MORPHOLOGY OF ERYTHEMA NODOSUM

The typical morphologic features of erythema nodosum need not be described, as the classical features are familiar to all. However, there are many atypical variants, the recognition of which is often difficult and the

status of which is generally uncertain. The ordinary evolution in the manner of a bruise (*dermatitis contusiformis*) is occasionally lacking or inconspicuous, the lesions presenting a delicate rosy hue or a faint purplish blush. Rarely, the eruption may be disposed unilaterally (diagnosed commonly as osteomyelitis, erysipelas, or septicemia) or a few efflorescences may appear on the contralateral limb either simultaneously or subsequently. While the lower extremities are the favored sites, it is not uncommon to find crops of lesions, usually of the small papular type, scattered on the upper extremities, notably about the elbows and wrists. In atypical situations, as on the face, lesions frequently reveal marked exudative qualities simulating the erythematovesicular type of erythema multiforme exudativum. In a considerable percentage of cases, eye lesions diagnosed as phlyctenular conjunctivitis or as episcleritis have been encountered, that these manifestations represent either rheumatic or tuberculous changes seems to be unproved as yet, though many investigators are in favor of the tuberculous etiology. Other observers have recorded the occurrence of oral mucous membrane lesions, an extremely rare manifestation with uncertain status. Lendon described splinter hemorrhages under the nails (Verco's sign) as part of the clinical picture of erythema nodosum. However, this phenomenon has not been encountered by other observers as well as myself and its status is also considered *sub judice*, painful subungual splinter hemorrhages are most commonly met with in subacute bacterial endocarditis, while, more rarely, massive extravasations of blood into the nail beds may be seen in "systemic" lupus erythematosus. The pseudo-fluctuant character of many lesions of erythema nodosum is probably caused by liquefaction of the neighboring subcutaneous fat when the inflammatory process affects the panniculus adiposus, but spontaneous resolution occurs without resultant necrosis or ulceration of the overlying skin. When an eruption is composed of elements that break down, there is reason to doubt the validity of the original diagnosis of erythema nodosum.

Galloway⁴² stated that he had observed two types of lesions in this skin disorder, the papular and large nodular varieties. However, he made no attempt to differentiate them etiologically, nor did he cite illustrative cases. In a more recent publication, Collis¹³ has proposed separation into the following two morphologic and etiologic categories, first, the large nodular flouid type attributed to rheumatic fever or, more generally speaking, to streptococcal infection, second, the small nodular (papular?) form associated with tuberculosis. Relative to the rheumatic variety, the evidence presented, thus far, to adduce a relationship appears to be inconclusive. Although the classification advocated by Collis is not entirely acceptable on morphologic grounds, it has the merit of stimulating interest in clinical minutiae as a means of etiologic differentiation.

It is not my purpose to discuss fully the differential diagnosis from a strict dermatologic point of view but rather to point out certain principles illustrating pitfalls in the classification of eruptions simulating erythema

nodosum In making this attempt the account will necessarily have to be incomplete, as the principal design will be to draw on personal observations, completing them with the opinions of other investigators. It will be shown that much of what has been quoted in the literature as erythema nodosum belongs in reality to another category of disease.

(a) *Erythema Multiforme Exudativum* This disorder, originally described by Hebra, presents a series of typical clinical phenomena, and in its ordinary form is easily differentiated from erythema nodosum. Like the latter disease, it has also been attributed to "rheumatism" but the evidence speaks clearly against this view (Tachau, Keil). The dermatosis may be associated with lesions on the lower extremities where, owing to the influence of location, they are apt to be somewhat nodular, show a cyanotic hue, and reveal tenderness on palpation (Veiel⁴³). This variation has been attributed, in large measure, to the superimposition of an element of circulatory stasis and it is this type that is often described as erythema multiforme exudativum combined with erythema nodosum. There are, however, occasional border-line instances, notably when erythema nodosum takes on exudative qualities, where differential diagnosis is most delicate. Despite the latter occurrence, it would be unwise to regard the febrile forms of these disorders as identical, without further study of so-called transitional instances. In its classical form, erythema multiforme exudativum, a well-characterized disease, differs radically in the location, morphology, and clinical course of its skin and mucous membrane manifestations.

(b) *Erythema Multiforme of Rheumatic Origin* Here we enter on a somewhat delicate subject. Many years ago Garrod³² recognized the influence of the factor of location on the morphology of rheumatic dermatoses, when he described papular and margined eruptions on the trunk in association with nodular painful lesions on the lower limbs. Josias⁴⁴ mentioned a similar observation. I have encountered an example of the phenomenon displayed by isolated lesions situated on the inferior extremities in a case of active rheumatic heart disease, to have labeled this eruption as erythema nodosum would have been stretching the point far beyond the criteria set down for the diagnosis of the latter disorder. Such dermatoses are always labeled erythema nodosum hesitatingly, though a review of clinical charts many years later may not lead to recognition of the uncertainties of the original diagnosis. In any event, the occurrence of small, somewhat painful lesions in the course of rheumatic fever does not necessarily mean that the eruption in question was that of erythema nodosum. The principle that skin lesions situated on the lower limbs may acquire attributes simulating erythema nodosum is also borne out by study of other dermatoses.

(c) *Chronic Bacteremia* Isolated skin lesions of painful and nodular character may be encountered occasionally in the course of various forms of bacteremia in the acute as well as the more chronic types, but notably in the latter variety (subacute bacterial endocarditis, chronic meningococcemia,

gonococcemia, enterococcemia, etc.) Because of their physical attributes, these eruptions are often classed as examples of atypical erythema nodosum, unlike the latter disorder, the lesions are generally discrete and few in number, are situated at other sites of predilection (especially the upper limbs), do not show the characteristic gamut of color changes, and undergo involution in a short time, usually measured in hours to one or two days. In their physical characteristics, they are strikingly analogous to the Osler Node a term generally applied to the painful lesions observed on the finger tips, toes and other parts in subacute bacterial endocarditis. I have seen cases of chronic bacteremia diagnosed as rheumatic fever because of the presence of skin lesions, fever, polyarthralgias, functional or organic heart murmurs, and even prolongation of the P-R interval in electrocardiograms. Blood culture studies are usually of prime aid in establishing a correct opinion, sometimes the finding of the causative organism in sections of skin may provide the first clue. The difficulties confronting the clinician in the face of nodular painful eruptions accompanied by a clinical picture resembling rheumatic fever are therefore apparent. These skin lesions are not representative of true erythema nodosum and should not be labeled with this name, otherwise, the subject will become necessarily complicated by the introduction of miscellaneous dermatoses.

(d) *Tuberculides* There is a more acute variety of erythema induratum revealing transitions to papulo-necrotic tuberculides and resembling erythema nodosum. Of this variant I have encountered three examples, characterized by the occurrence of cervical lymph node tuberculosis, typical papulo-necrotic lesions about the elbows, and painful, purplish red, nodular efflorescences on the lower limbs. The latter simulated ordinary erythema nodosum, the resemblance being further promoted by the failure to ulcerate and the assumption of an intense purple hue in the course of gradual involution. They differed, however, in their longer duration, in their association with typical lesions of papulo-necrotic tuberculides (some of which failed to show the characteristic central necrosis), and in the presence of chronic active tuberculosis of the lymph gland variety. It is possible that this type may be more properly labeled as papulo-necrotic tuberculide with atypical lesions on the lower extremities, the physical attributes of the latter being markedly modified by location.

I have also encountered several examples of non-ulcerating erythema induratum (Bazin type) in which the dermatoses were diagnosed as erythema nodosum owing to the painful nature of some of the lesions. It is possible that cases of this type may be given the title of chronic erythema nodosum. It is my belief, however, that erythema nodosum is chronic only in the sense that many relapses of the eruption may occur or, in the absence of recurrent cutaneous manifestations, that constitutional symptoms, such as fever, continue unabated over a relatively long time, the appearance of skin lesions for many weeks is not necessarily an indication of longevity.

in the individual efflorescences, but rather is ascribable to the superimposition of fresh crops on fading lesions

(e) *Syphilides* It appears from the accounts of several observers, notably that of Hoffmann,⁴¹ that there are instances of secondary syphilides resembling ordinary erythema nodosum. The precise status of this rare group is still unsettled, some of the cases seem to be instances of secondary syphilides with specific involvement of blood vessels of the lower limbs and elsewhere, resulting in skin lesions apparently indistinguishable from erythema nodosum, others may be examples of coincidental banal erythema nodosum, still others, of drug eruptions particularly those caused by iodides or bromides, and, finally, some cases may represent instances of gummas that have resorbed completely without concomitant ulceration. The importance of this group of cases, as described by Hoffmann, lies in (1) the possible confusion with banal erythema nodosum, (2) the similarities in clinical picture to that of rheumatic fever, since in several of the recorded examples "rheumatic pains" occurred (syphilitic periostitis?) and in occasional instances the joints were said to have been swollen and red. Since the publication of Hoffmann's comprehensive report of 11 instances of secondary syphilides resembling erythema nodosum, there have been but few additions to the casuistic literature and these, for the most part, doubtful in nature. How confused the subject has become is indicated by the citation (Spink³⁰) of Stillians and Seneai's⁴² case as one of erythema nodosum syphiliticum, this case presentation provoked considerable debate relative to the status of the eruption and it seems interesting that the subsequent course revealed ulceration of the nodules in the manner of gummas. This instance cannot, therefore, be classified as an example of erythema nodosum. The entire subject of erythema nodosum syphiliticum is in need of clarification. No convincing proof has been recorded as yet that ordinary erythema nodosum may be a syphilitic manifestation, it is, however, granted that secondary and tertiary syphilitic skin lesions may occasionally present close clinical similarities to ordinary erythema nodosum.

(f) *Skin Lesions of Ulcerative Colitis* The statement that erythema nodosum occurs in the course of chronic ulcerative colitis (Spink) has been based on the statistics furnished by Baigen⁴³ who in 693 cases of this disease, found 17 instances exhibiting skin lesions, particular mention having been made of erythema nodosum, no detailed case reports are, however, available so far as I was able to ascertain. From my own comparatively meager observations, it appears that this chronic disorder may be complicated occasionally by eruptions composed of nodular, painful, bluish red lesions, often called erythema nodosum at first sight, yet, further observation has revealed significant differences. In one striking instance, for example, the lesions which were situated on the lower limbs, and which at first seemed to be those of ordinary erythema nodosum, became filled with fluctuant bags of pus and then proceeded to break down. In another case efflorescences, similarly located, ulcerated rapidly. In still another example, there appeared

crops of painful, dull red papules over the upper and lower limbs, the dermatosis, however, lacking the ordinary physical attributes of erythema nodosum. The resemblance to erythema nodosum may be further promoted by the occurrence of joint symptoms which may occur in the course of chronic ulcerative colitis itself. Other observers have recorded analogous instances which may be conveniently divided into two arbitrary groups with transitions. (1) ulcerative lesions on the lower limbs, commonly termed pyoderma gangrenosum (Brunsting, Goeckerman, and O'Leary,⁴⁸ and Cohen⁵⁰ among others), larger areas of necrosis may also occur on other parts of the body, such as the trunk, (2) eruptions composed of efflorescences that early in the course may simulate erythema nodosum strikingly, but where subsequent observations reveal either spontaneous breaking down of lesions (Brooke⁴⁹) or the formation of subcutaneous abscesses (Jones⁵¹). While the latter group may at first give rise to the clinical impression of ordinary erythema nodosum, it is apparent that the resemblances are superficial and occur only in the early course of the eruption. In studying the cutaneous manifestations of a disease like chronic ulcerative colitis which has experienced the gamut of medicinal therapy, it seems necessary to eliminate the possibility of drug etiology in every case of the disease.

(g) *Drug Eruptions* This leads us into one of the most interesting and difficult phases of the problem, a more detailed consideration of which seems advisable in view of the high incidence of nodular painful eruptions of drug etiology.

It has been stated by Tachau¹ that nodular erythemas caused by drugs are distinguishable from ordinary erythema nodosum by virtue of the following features, their location may be atypical, the nodules are fewer in number and reveal tendency to necrosis, characteristic color changes do not appear in their further evolution, constitutional symptoms are lacking, and, finally, the eruption disappears when the suspected drug is stopped. However, these differential points do not hold for all cases, as there are many exceptions to the above stated rules. It is common knowledge, for example, that various medications may give rise to lesions that may simulate ordinary erythema nodosum in every morphologic detail. The problem becomes further complicated when drugs are administered for the alleviation of constitutional symptoms such as fever and joint pains of various causes. However in the average case absence of constitutional symptoms may be regarded as favoring drug etiology but the latter should be verified by history of ingestion of the suspected medication, suitable laboratory tests (for example, urine examination for detection of bromides etc.), and by other cutaneous evidence, such as the observation of a pustular eruption appearing simultaneously (iodides, bromides, etc.). In several instances of "halogen" erythema nodosum I have observed deep subcutaneous nodules which did not directly affect or discolor the overlying skin, substantiating Schidach's³ observations on iodide (nodose) eruptions, this phenomenon

is also encountered occasionally in idiopathic erythema nodosum, for reasons which have already been detailed

Several difficulties may arise in determining the etiology of drug eruption simulating ordinary erythema nodosum. First, the history of ingestion of medication may be inadequate, second, laboratory procedures may be required to demonstrate the suspected drug, third, the patient may refuse to submit to therapeutic tests for purposes of reproducing the lesions *ex juvantibus*, fourth the absence of constitutional symptoms may not necessarily indicate a drug etiology as there are instances of banal erythema nodosum characterized by minimal or insignificant systemic reactions. It seems advisable to discuss these points which are commonly met with in dermatologic practice and which are sources of great difficulty. Appreciation of these difficulties is essential to the understanding of the problem as it relates to rheumatic fever. Dreschfeld⁵² was among the first to suggest the possibility that lesions of erythema nodosum appearing in the course of rheumatic fever might be due to the ingestion of salicylates as he had personally observed this occurrence. Hegler recorded a case of rheumatic fever in which sodium salicylate produced a dermatosis simulating banal erythema nodosum, it differed, however, in the attendant pruritus and lack of color changes in its further evolution. Coburn described an instance of rheumatic erythema nodosum but the clinical attributes, such as itching and overlying vesicles, warrant suspicion of possible drug etiology, a dermatosis exhibiting these characteristics can hardly be classed as a typical example of erythema nodosum. In addition to salicylates, there are other drugs capable of producing skin lesions simulating banal erythema nodosum, among these may be mentioned quinine compounds, iodides, bromides, pyrimidon, etc. It will be recalled, as a point of historical interest, that quinine and, in particular, potassium iodide were widely used in the treatment of rheumatic fever during the middle of the nineteenth century. The frequency with which iodides, for example, are capable of causing nodose painful eruptions is well known today, but apparently older observers were not aware of this point or did not take it sufficiently into account. On the other hand, there is a great tendency to suspect drug eruption merely because medication has been administered, leading inevitably to errors in diagnosis. Each case must, therefore, be individualized and, whenever feasible, an attempt should be made to prove the nature of the dermatosis by *controlled* therapeutic tests which, in final analysis, furnish the most decisive proof.

However, this procedure carries with it the possibilities of certain errors which should be recognized. (1) a given single dose of a drug may not reproduce the dermatosis *ex juvantibus*, in other words, eruptions are not always caused by marked hypersensitivity to a small quantity of medication, rather, a definite concentration of substance must be reached in the tissues before skin lesions occur. It is common knowledge, for example, that patients may take iodides or bromides for a long time before a dermatosis appears. I have also observed a case of "fixed" eruption caused by venereal,

where 10 grains of the drug reproduced the eruption, whereas 5 grains were without effect. The occasional statement found in the literature with respect to a latent period following the onset of a drug dermatosis, during which period the suspected medication is incapable of reproducing the skin lesions, needs substantiation in the light of the foregoing remarks. (2) It is necessary in trying the tests to eliminate the possibility of spontaneous relapses of the cutaneous manifestations, an especially common occurrence in erythema nodosum. It does not seem, however, from recent experimental work, that this factor has been sufficiently appreciated, and, unless one is exceedingly cautious, etiologic conclusions based on "therapeutic fallacies" may be drawn. Nonspecific effects also need to be recognized and evaluated.

It will be seen, therefore, from the foregoing comments, how many difficulties may present themselves in the diagnosis of an eruption as true erythema nodosum and how much care is necessary if one wishes to attack this problem in as scientific a manner as the subject permits.

SUMMARY AND CONCLUSIONS

The hypothesis that erythema nodosum represents one of the rheumatic series had its roots in the original communications by S. Mackenzie who was instrumental in popularizing it. This was accomplished during an era when the term rheumatic disease did not enjoy the precise meaning which it now possesses, the criteria employed by Mackenzie were, therefore, vague and much too elastic, a circumstance recognized by many of his contemporaries whose dissenting opinions were cited. Mackenzie's views are, however, still widespread among practitioners and, indeed, his statistical evidence is still quoted as corroborative of the hypothesis. When the diagnosis of rheumatic erythema nodosum is postulated, there is automatically conveyed to the mind of the observer the potentialities of subsequent serious cardiac disease, and it is for this reason that the subject assumes an importance far beyond the theoretical implications.

A number of recent investigators, recognizing that many cases reveal no evidence of rheumatic fever at any time, have adopted the eclectic point of view that a certain variable percentage of erythema nodosum is of rheumatic origin. Too often such beliefs are based on impression and no serious effort made to ascertain the fate of such patients. Complicating the problem has been the attempt of some observers to separate the disease as seen in children from that in adults, a point of view that does not seem to be corroborated by study of the disorder in all age-groups. When one analyzes the characteristics of the genuine rheumatic dermatoses (papular, marginated, and flat circinate erythemas of rheumatic fever), there appears reason to doubt that erythema nodosum belongs in the same category. As argument by analogy alone may prove treacherous, it was decided to study the entire subject in a critical manner.

At the outset, it must be emphasized that a condition as common as is rheumatic heart disease may be associated sometimes with erythema no-

dosum appearing as a coincidental and unrelated affection. It is probable that if observers were to look back upon their clinical experience, they would recall an occasional case of this type, where the occurrence of skin lesions had no appreciable effect on the heart disorder clinically, where the eruption resolved in a short time and the patient recovered within a correspondingly brief period without any mishap. In the text there were noted, also, two examples of coincidental erythema nodosum, probably of drug origin, appearing in patients afflicted with chronic inactive rheumatic heart disease, accompanied by mild congestive failure apparently of mechanical nature. What, on the other hand, is to be expected in persons who have never suffered from any of the various rheumatic stigmata, and who present, for the first time, the cutaneous manifestations of erythema nodosum at the inception of a febrile illness, accompanied by joint symptoms and other phenomena? Do these patients develop undoubted evidence of rheumatic heart disease?

The relation of such instances to rheumatic fever was analyzed in terms of the criteria set down for the diagnosis of the latter disease (sore throat, joint involvement, cardiac disease, chorea, subcutaneous nodules, pleurisy, salicylate therapy, active vs. inactive rheumatic disease, comparison with known rheumatic erythemas, and the pathologic features). The data recorded seemed to indicate that this alleged relationship rested on tenuous grounds, in many instances it was apparently not realized that the two disorders may present similar but not necessarily identical or superimposable features, resemblances in clinical picture do not connote absolutely alliance between such conditions. It was further noted that many eruptions, frequently quoted in the literature as true erythema nodosum, were in all probability manifestations of another category of disease. This point was illustrated by brief citation of disorders confounded with erythema nodosum as seen within my own observations (erythema multiforme exudativum, erythema multiforme of rheumatic fever in its papular and margined forms, skin lesions encountered in acute and especially in chronic forms of bacteremia, tuberculides of the papulo-necrotic or erythema induratum types, syphilides, cutaneous manifestations of chronic ulcerative colitis, and, most important of all, the nodular, painful eruptions of drug origin). Chief emphasis was placed on the principles illustrating pitfalls in diagnosis, rather than on a close dermatologic consideration of morphologic minutiae. It becomes apparent, in studying a problem of this sort, that the internist cannot rely solely upon his own knowledge of cutaneous manifestations, that reports in the literature must be evaluated with a critical eye, and that studies based on perusal of charts, while valuable and instructive, take second place to personal observation. Too often valuable details relative to eruptions are not recorded or a diagnosis of erythema nodosum may be made diffidently in the hope of subsequent confirmation which may not be forthcoming but which is not apparent to the person reviewing the chart at a later date.

The relation of erythema nodosum to rheumatic fever is, therefore, a problem which should be investigated anew. Cases of this type must be studied over long periods of time in order to eliminate with certainty the possibility of clinically unrecognizable rheumatic heart disease. Every method of approach must be utilized, but the limitations of the various procedures must also be recognized. In patients with inactive rheumatic heart disease, erythema nodosum or lesions resembling it, may occur (*a*) coincidentally, (*b*) as a drug eruption, (*c*) as evidence of rheumatic activity, (*d*) under the guise of an erroneous diagnosis. In persons showing undoubted evidence of active rheumatic heart disease (rheumatic fever), the skin lesions may appear (*a*) fortuitously, (*b*) as a drug eruption, (*c*) as a genuine manifestation of rheumatic origin, (*d*) as part of the nodose lesions seen in rheumatic erythemas, (*e*) as a wrong diagnosis. With regard to true erythema nodosum, it would seem advisable to study the disorder under two heads: (1) in its ordinary primary form, where the lesions appear at the inception of disease without previous evidence of rheumatic fever, (2) where the eruption occurs in a patient who is already known to be afflicted with rheumatic heart disease or has had stigmata of rheumatic fever. My own observations do not appear to substantiate the hypothesis that erythema nodosum is of rheumatic origin, even when preceded by sore throat and followed by joint manifestations. It will not do to label cases of erythema nodosum as tuberculous when the tuberculin test is positive and rheumatic when the reaction is negative.

THE RELATION OF FUNGUS INFECTION OF GRAIN CROPS TO VASOMOTOR DISTURBANCES IN MAN

By JACOB E. KLEIN, M.D., *Chicago, Illinois*

THE relationship of diseases of plants to human health has not received the detailed consideration which it deserves. Although botanists and agriculturists have made intensive studies of plant pathology, there has been no systematic effort to correlate plant disease with human pathology. On perusing the literature with a historical perspective it is interesting to note that the ancients ascribed disease conditions to contaminated cereal crops. Thus Galen refers to the "morbus cerealis," a disease due to eating spoiled cereal. There are also on record epidemics from eating bread made of rye infected with the fungus, *Claviceps purpurea*.¹

Robertson and Ashby² have reported on the symptoms of ergotism found among the Jewish people of Manchester as the result of eating rye bread. The symptoms complained of were coldness in the extremities, numbness and lack of sensation in the fingers, formication, headache, gastric disturbances, shooting pains, twitchings in the limbs, and staggering gait. None of the symptoms were observed among those of the Jewish population who ate white bread. The rye grain examined at Manchester showed an incidence of 1 per cent infected with fungus.

Although the occurrence of epidemics of ergotism is a well known medical fact the widespread infestation of our cereal crops with *Claviceps purpurea*, *Ustilago zeae*, *Fusarium moniliforme* and other grain fungi has been rather overlooked or neglected as a fact of medical importance. *Claviceps purpurea*, the ergot fungus, occurs commonly on rye (*Secale*), and many other species of grass such as wheat grass, wild ryes, Kentucky blue grass, Canada blue grass, red-top, timothy grass, and occasionally wheat. The mycelium of the ergot fungus attacks the ovary of the plant while it is in bloom. The fungus consumes the ovary and replaces it with the ergot which consists of a dense mass of fungoid interwoven mycelium, a sclerotium (figure 1). Cattle fed ergotised grain or grass become emaciated and rough-haired. There is a disturbance in the circulation through the extremities, and gangrene of parts of the tail, ears, and hoofs may occur, as well as abortion.

After having published my preliminary report³ on the etiologic relationship of these grain infestations to vasomotor disturbances such as erythromelalgia, Raynaud's disease, Buerger's disease, Schultz's acroparesthesia, acrodynia, and hypertension it was called to my attention that J. Kaunitz⁴ in 1930 had contributed a report on the pathologic similarity of thromboangitis obliterans and endemic ergotism. His is the first report that I have

* Received for publication May 1, 1936.

From department of Pediatrics, Northwestern University Medical School, and the Laboratory of Pathology and Bacteriology, Northwestern University Dental School.

read which attempts to establish the theory that ergotism of a chronic endemic type is responsible for Buerger's disease and related vasomotor disturbances. He notes that the ergot fungus attacks most of the grains and grasses and is present in most portions of the globe. It has been reported in every continent including Australia and New Zealand. Considering the amount of ergot-infected rye bread consumed, Kaunitz is surprised that cases of endemic ergotism are so rarely reported. He further states that it may well be that such conditions as thromboangitis obliterans, Raynaud's

FIG 1 Sclerotium of ergot fungus

disease, as well as other vasomotor and trophic disturbances have been overlooked as possible sequelae to ergot poisoning. This may be because of the mildness of the original intoxication and the insidious onset of the vascular changes. Kaunitz further notes that both thromboangitis obliterans and gangrenous ergotism have a preference for the male sex.

Another aspect of ergotism has been reported by Mellanby⁵ who has demonstrated a very important fact with regard to diet and ergot toxin. On the basis of experimental studies he concluded that food rich in vitamin

A prevents the neurotoxic effects of ergot toxin, while a deficiency in vitamin A increases the degenerative effect of this poison. Furthermore, the addition of cereals and cereal embryo aggravated the degenerative changes induced by the ergot poison. Mellanby demonstrated experimentally that ergot could be consumed with impunity as long as the diet was rich in vitamin A and carotene. This fact is of decided clinical and therapeutic significance.

In the course of the present work I have examined samples of commer-

FIG 2 Conidiospores of ergot parasite in commercial rye flour

cial rye flour and pumpernickel bread (whole rye much used by our immigrant population, particularly Slavs) and have been able to demonstrate the conidiospores of the ergot parasite (figure 2). I have also examined corn meal bought in the retail market and have found the spores of *Ustilago zae-mays* (figure 3). Corn is very frequently diseased (figure 4). Among the most common types of corn infestation are the smut fungi, *Ustilago zae* (Koehler⁶). The outstanding characteristic of all the grain smuts is that they nearly always destroy the head or grain of the wheat, rye, barley, corn or oats affected. There are more than 600 species of these

grain parasites recognized, of which 205 are found in the United States. It is estimated by F. L. Stevens and J. B. Hall ⁷ that 100,000,000 bushels of grain are affected annually by the development of smut on corn, wheat, oats, rye, and barley. The common corn smut develops on any part of the corn plant but is much more conspicuous on the ears and tassels.

Intoxication occurring in children with all the symptoms of acrodynia has been reported by E. Mayerhofer ⁸. In the spring of 1929 he observed two children from the region of Zagreb who presented all the manifestations

FIG 3 Spores of *Ustilago zeae-mays* from cornmeal

of ergotism or acrodynia and who had been fed on contaminated corn. A large content of *Ustilago zeae* spores was found in the corn flour. The intoxication had the pharmacologic and toxic characteristics of ergotism. Mayerhofer has expressed himself as seeing a causal relation between corn smut and acrodynia.

I have isolated *ustilago* spores from commercial corn meal and cultured them on sterilized corn meal media. After a heavy growth was obtained it was extracted with acid alcohol. The resulting product when injected into

an adult rooster caused a blackening of part of the comb, thus demonstrating the ergot effect and the vascular toxicity of the *ustilago* fungus. Sollmann⁹ in his pharmacology notes that corn smut, or *Ustilago zeae*, has a mild ergot action and is frequently used to induce abortion among Southern negroes. A. Marie¹⁰ made extracts of diseased corn and found that it had the properties of ergot.

The chemistry of ergot has been the subject of numerous thorough investigations. Various substances such as amines and alkaloids have been extracted. Dale¹¹ found that the action of ergot was due to the presence of

FIG. 4. Incubated corn kernel with *ustilago* fungi growing

ergotoxine, tyramine, and ergamine. More recently Stoll¹² has isolated a crystalline alkaloid, ergotamine tartrate ($C_{22}H_{32}N_2O_8$), which is a chemically pure alkaloid and which has marked potency. It is a pharmacologic antagonist to adrenalin and inhibits the sympathetic nerve endings. It lowers the basal metabolism, causes a diminution in heat production and has a marked action on the uterine musculature. In a dilution of 1-2,000,000, it acts on the guinea-pig uterus and is thought to be the specific alkaloid of ergot. Human beings have been found to be more sensitive to its effects than animals.

I studied the effect of ergotamine tartrate on the white rat. A group of six young white rats were used for the ergotamine experiments and four were held as controls. A solution of two and one-half mg of ergotamine tartrate was injected subcutaneously twice weekly for two months. The drug was also administered daily in the drinking water in the proportion of 0.001 gm to 8 ounces of water. Early in the experiment there was noted a pronounced cyanosis of the tip of the tail in all of the six experimental rats. A dry gangrene of the tail developed in two rats after the first month. The experimental animals seemed quieter than the controls. One, however,

FIG 5 Normal artery of rat's tail

developed symptoms of excitation, ran about the cage, made unusual noises, and acted in a strange manner. After two months all of the animals were chloroformed and autopsied. No noteworthy abnormalities were found on the gross examination. On histologic study the tail arteries of the experimental rats were found to be very markedly constricted so that almost no lumen was apparent (figures 5 and 6). No inflammatory changes were observed.

The various theories proposed at present for the explanation of acrodynia do not seem to be satisfying or conclusive. Feer¹³ has suggested that

the condition is a neurosis of the vegetative nervous system. This is considered plausible by many. Others, on the contrary, ascribe it to some unknown virus infection or even to a deficiency of vitamins. The pathologic findings in the few cases studied have been rather puzzling and unsatisfactory. Most of the attention has been centered on the state of the nervous system with very dubious results.

In view of the conflicting theories on the etiology of acrodynia, the theory that it is due to grain fungus intoxication is brought up for consideration on the basis of the above clinical and experimental data.

FIG 6 Constriction of artery after ergotamine

CONCLUSIONS

1 Our common cereals are frequently subject to fungus infection, particularly *Ustilago* (smut) and *Claviceps purpurea* (ergot).

2 It is suggested that the ingestion of such food over a period of years may produce a chronic intoxication by the contained ergot alkaloids and amines which may be the cause of certain vasomotor disturbances such as acrodynia, Buerger's disease, erythromelalgia, Raynaud's disease, and acroparesthesia.

3 It seems advisable that serious attention be given to the problem of reducing these fungus infections of our common cereals by modern chemical treatment of infected seed and by improved milling methods

4 Plant pathology is of considerable significance in relation to human health and should be systematically studied from this point of view

CASE REPORTS

BRADYCARDIA IN APPENDICITIS, REPORT OF A CASE[†]

By MITCHELL BERNSTEIN, M D, F A C P, and RALPH GOLDSMITH,
M D, F A C S, *Philadelphia, Pennsylvania*

THE occurrence of bradycardia in a patient manifesting acute abdominal symptoms which proved to be due to a gangrenous appendix prompted us to investigate this subject. It is interesting to note that in *The Journal of the American Medical Association* of December 1906, Maurice Kahn¹ directed attention to the presence of bradycardia in appendicitis. He stated that "in the last six cases of gangrenous appendicitis in which this symptom was evinced, the diagnosis of the gangrenous state was made before operation, based on the bradycardia alone. So it would appear from this that given a case presenting other unmistakable signs of appendicitis with a subnormal pulse, the tentative diagnosis of gangrene, with some reason, may be maintained."

Since the appearance of Kahn's original article several French and German authors have added other cases of similar nature to the literature. Von Bokay² in 1908 cited 10 cases of bradycardia in appendicitis in children. Although Kahn believed that the bradycardia in appendicitis was due to the absorption of ptomaines which acted on the cardiac centers or ganglia, Bokay believed the mechanism to be due to vagal stimulation. Broca³ reported an instance of cardiac arrhythmia occurring in non-gangrenous appendicitis which was corrected when the appendix was removed and even before the patient had recovered from the anesthesia. Other cases in his experience of appendicitis and bradycardia are cited in which gangrene did not occur but abscess and adhesions were present. He emphasized the importance of observing the pulse and temperature relation in making a prognosis and determining the time for operation.

Vaquez⁴ suggested the use of atropine to differentiate reflex bradycardia from that associated with a myocardial lesion of infectious origin. He reported a case in which a nervous patient in the course of an attack of appendicitis had considerable and persistent slowing of the pulse (40 per minute) with slight syncopal attacks. Atropine doubled the pulse rate and both the bradycardia and the syncope disappeared. Apparently, on the basis of this experience Vaquez and Lairdlow⁵ state that "it has been asserted that the bradycardia is a sign of danger, but this is an error. In one of our patients the bradycardia disappeared after the injection of atropine." These authors point out that bradycardia occurs in many different diseases, notably abdominal diseases and especially in appendicitis.

Loeper⁶ reported a fatal case of appendicitis with bradycardia, that of a man, aged 38, with sudden onset of vomiting following right lower quadrant pain and fever. Improvement followed upon the application of an ice cap.

[†]Received for publication October 5, 1936.

From the Medical Service of Dr. Mitchell Bernstein and the Surgical Service of Dr. Ralph Goldsmith, Jewish Hospital.

On the third day, abdominal distention occurred, with pinched facies. The pulse which was 110 per minute lowered suddenly to 50 per minute despite the persistence of fever. Laparotomy revealed a gangrenous appendix and a collection of pus. Although drainage was instituted, a subphrenic abscess and right pleurisy followed and death occurred on the eleventh day after operation.

Benard⁷ studied the bradycardia in appendicitis by phlebogram tracings.

Decourt and Bascourret⁸ observed that the concept of bradycardia of gastrointestinal origin seems much less well established than the usually accepted belief that certain gastrointestinal conditions may reflexly produce palpitation, precordial pain, tachycardia and extrasystoles.

THE MECHANISM OF THE REFLEX BRADYCARDIA

The mechanism of reflex bradycardia is explained by Howell⁹ as follows: "The inhibitory fibers of the heart may be stimulated reflexly by action upon various sensory nerves or surfaces. One of the first experimental proofs of this fact was furnished by Goltz's¹⁰ often quoted 'Klopfversuch'. In this experiment, made upon frogs, the observer obtained standstill of the heart by light, rapid taps on the abdomen and the effect upon the heart failed to appear when the vagi were cut. In the mammals every laboratory worker has had numerous opportunities to observe that stimulation of the central stumps of sensory nerves may cause a reflex slowing of the heart beat. The effect is usually very marked when the central stump of one vagus is stimulated, the other vagus being intact. The vagus carries afferent fibers from the thoracic and abdominal viscera, and most observers state that the heart may be reflexly inhibited most readily by stimulation of the surfaces of the abdominal viscera, by a blow upon the viscera, for example, or by sudden distention of the stomach. In man similar results are noticed very frequently. Acute dyspepsia, inflammation of the peritoneum, painful stimulation of sensory surfaces, the testes, for instance, or the middle ear, may cause a marked slowing of the heart,—a condition designated as bradycardia. What takes place in all such cases is that the efferent impulses carried into the central nervous system reflexly stimulate the nerve cells in the medulla which give origin to the inhibitory fibers of the heart."

The perennial question of the differential diagnosis between thoracic disease with abdominal symptoms and vice versa still remains an important problem in medicine. For instance, a case in point is acute coronary occlusion with its referred abdominal symptoms which often simulate gall-bladder disease. In our patient, the first symptoms suggested an acute surgical abdominal condition, but with the temporary subsidence of the abdominal symptoms, and the persistence of the bradycardia, it appeared that we were dealing with some cardiac derangement. However, the true nature of the process soon became apparent with the localization of the pain and the tenderness.

CASE REPORT

F. M., an unmarried man, aged 30, was admitted to the accident ward of the Jewish Hospital on December 22, 1935 at 4 a.m., complaining of severe abdominal pain which had come on rather suddenly and had persisted for over two hours. The pain which was quite diffuse was of a dull aching character. Flatulence and belching were present but there was no nausea or vomiting. On admission, the patient's

temperature was 95° F, and the respirations were 16 per minute. A striking feature on examination was the cardiac rate which was recorded at 44 per minute. The cardiac examination otherwise was negative. The systolic blood pressure was 120 mm of Hg and the diastolic pressure was 80 mm. Physical examination other than the foregoing was essentially negative.

The patient stated that he had had "encephalitis" for two weeks in 1922, from which he had apparently recovered. His tonsils had been removed in that year. He could not recollect any history of chorea, rheumatic fever or cardiac disease.

Following the routine physical examination, a fluoroscopic examination of the abdomen was made and was reported as negative.

At 11:30 a.m. seven and a half hours following admission to the accident ward the patient appeared quite comfortable and was free of pain. Curiously enough the bradycardia persisted, the heart rate averaged 42 beats per minute. Electrocardiographic study (figure 1) made at that time showed a sinus bradycardia of normal rhythm and a cardiac rate varying from 42 to 53 per minute.

Fig 1 Sinus bradycardia with ventricular rate varying from 42 to 53 per minute

In view of the bradycardia associated with the acute abdominal symptoms, the patient was advised to remain in the hospital and he was admitted to the medical service of Dr. Mitchell Bernstein.

A blood count showed 10,850 leukocytes and 61 per cent polymorphonuclear cells, 36 per cent lymphocytes, two transitional cells and one eosinophile. Examination of the urine was normal.

On the afternoon of December 23, the day following admission, the patient again complained of pain, now localized to the right lower abdominal quadrant. Examination disclosed tenderness and muscular rigidity over this region, and the diagnosis of appendicitis was made. At 3 p.m. the cardiac rate rose to 70 per minute while the temperature was 102.6° F. A second electrocardiographic study (figure 2) showed a normal sinus rhythm with a cardiac rate of 68 per minute. The blood study showed 90 per cent hemoglobin, 4,650,000 red blood cells and 13,000 leukocytes per cu. mm. with 85 per cent polymorphonuclear cells and 15 per cent lymphocytes.

FIG 2 Normal sinus rhythm with ventricular rate of 68 per minute

FIG 3 December 24, 1935 Following operation Sinus bradycardia with ventricular rate of 56 per minute

FIG 4 December 30, 1935 Seven days after operation Normal tracing with ventricular rate 77 per minute

In the early evening the patient's abdominal symptoms became more severe. Dr Ralph Goldsmith, concurring in the diagnosis of appendicitis, operated upon the patient immediately, under ether anesthesia, and removed an acute gangrenous appendix which was embedded in an omental pocket.

On December 24, the day following operation, electrocardiographic study (figure 3) curiously enough showed a cardiac rate of 56 per minute with a normal sinus rhythm. The patient's convalescence was uneventful.

Another electrocardiographic study (figure 4) on December 30, 1935, seven days after operation, showed a normal tracing with a cardiac rate of 77 per minute. Subsequent follow-up examinations of the patient on March 8, 1936 and July 2, 1936 showed the patient to be well. His heart rate was 72 per minute and following slight exertion it rose to 100 to 110 per minute.

DISCUSSION

As has been stated, Kahn in his original article on bradycardia and appendicitis, believed the bradycardia to be due to the absorption of ptomaines which acted on the cardiac centers or ganglia. However, Howell's explanation of bradycardia in abdominal diseases as being due to reflex vagal stimulation, is the generally accepted viewpoint. While an understanding of this reflex mechanism is of importance, yet from a practical standpoint the interest in Kahn's paper centers in the clinical recognition of the associated bradycardia in appendicitis, in so far as it may mean the ultimate saving of human life.

That the diagnosis of gangrenous appendicitis is often difficult, especially in cases where the symptoms are latent or deceptive, is a fact well known to the experienced physician. Since the treatment of appendicitis is purely surgical, and since the treacherousness of the disease increases as the lesion progresses, any new sign or symptom useful in establishing a correct diagnosis should be carefully considered.

In our case, herein reported, the gangrenous appendicitis might have been overlooked with a probably serious result. In fact, Loeper's case of somewhat similar nature proved fatal. Although other writers such as Broca and Benard have reported occasional instances of bradycardia in cases of nongangrenous appendicitis, this does not detract from Kahn's observation.

Because of the experience with our reported case, we should like to direct attention to and reemphasize the importance of Kahn's observation, namely that bradycardia occurring in association with abdominal symptoms indicative of appendicitis, is very suggestive of gangrenous appendicitis.

PERIARTERITIS AND ARTERITIS OF THE TEMPORAL VESSELS, A CASE REPORT *

By JOHN A MACDONALD, M D, F A C P, and ROLLIN H MOSER, M D,
Indianapolis, Indiana

ARTERITIS of the temporal vessels has recently been described as a new clinical entity by Hoiton, Magath and Brown¹ A case presenting similar clinical and pathologic data is the basis for this report

CASE REPORT

A married woman, white, aged 60, a housewife living in the country, entered the hospital March 1, 1935, because of pain in her temples, fever, sweats and general malaise About five weeks before admission she had noticed a tender area in front of her right ear A week later the left side of her face became swollen and tender to pressure At this time she became aware that the temporal arteries were very prominent and red and very tender Mastication was painful General malaise and weakness were pronounced, and fever and sweats were present every night She had had no recent acute infection or injury although she had been to a beauty parlor for a permanent wave a few weeks before the onset of her illness Her past history was of no importance She had been exceptionally free of respiratory and gastrointestinal disorders She had never had rheumatism, typhoid fever or malaria There were no genitourinary symptoms The menopause had occurred 12 years before There had been a moderate weight loss of six pounds during this illness Her father died from cerebral hemorrhage at sixty She gave no history of previous vascular disease

Physical examination revealed the left temporal artery to be very prominent from a point just above the temporomandibular joint for a distance of about two and a half inches It was thickened, tortuous, the caliber irregular and the surrounding tissue very hyperemic Pulsation was present throughout the course of the vessel at the time of the first examination although this became very much diminished a little later There were no palpable nodules present The right temporal artery was less acutely involved than the left but pulsation was definitely diminished The pre-auricular and postauricular glands were moderately enlarged and tender The right facial artery was somewhat indurated where it crossed the mandible but no other peripheral vessels were involved The pupils reacted normally to light and in accommodation Both nerve heads appeared normal and the retinal vessels showed about the usual change for her age Two teeth were found to have definite periapical infection The lungs were normal to physical examination The heart was not

* Received for publication August 17, 1936

grossly enlarged, a moderate tachycardia was present and a slight accentuation of the aortic second sound. A definite pulsation was felt in the suprasternal notch. The blood pressure was 148 systolic and 90 diastolic. A careful search of the skin and mucous membranes revealed no petechiae. The reflexes were intact and normal throughout and the vibration sense normal. The spleen and liver were not palpable and there were no masses, no fluid and no tender areas in the abdomen. Digital examination of the pelvis and rectum was negative. The average of several blood counts was as follows: Hemoglobin 71 per cent, red blood cells 3,580,000, white

FIG 1

blood cells 8,600, with a normal differential. The coagulation and bleeding times and the platelet counts were normal. The Wassermann test was negative. Two blood cultures were negative. Agglutination tests for undulant fever, typhoid and paratyphoid were all negative. Several urine specimens at the time of admittance contained a faint trace of albumin and an occasional hyaline and granular cast, later specimens were negative. The phthalein test was 59 per cent in two hours and the urea clearance was 52 cc. The basal metabolic rates were minus five and three. Roentgen-ray of the chest revealed a normal sized heart and a mild fibrosis throughout both lung fields. The temperature ranged from normal to 101.8° F with

a very irregular curve. The pulse rate varied from 90 to 120. At no time were there any abdominal symptoms, peripheral nerve pains or involvement of the joints. The patient was kept at rest in bed and hot moist compresses of magnesium sulphate solution were applied to the temporal arteries. Sodium salicylate and Lextron were given orally. On March 29, a section of the right temporal artery three centimeters in length was removed. Cultures were made of the tissue on various types of media and sections made for histological study. The microscopic examination made by Dr. H. M. Banks was reported as follows: "Sections taken through four levels of the cross section of the temporal artery show a structure which is almost devoid of lumen. The intima is markedly hypertrophied, narrowing the lumen to a very small

FIG 2 Low power showing temporal artery characterized by (1) narrowing of lumen, (2) massive hypertrophy of vessel wall, (3) edema of connective tissue surrounding the arterial wall and inflammatory cell infiltration of this connective tissue

point. The structure is homogeneous, somewhat hyalinized, and there is rather a scarcity of nuclear elements in the intima. The media shows almost total destruction and replacement by inflammatory cells of fibroblastic variety and by cicatrix formation. Immediately upon the exterior border of the media one finds in certain zones huge cells, irregularly round in contour, possessing many nuclei. These have the appearance of multinuclear native giant cells. The adventitia is quite narrow and atrophic in general appearance. The vasa vasorum shows hypertrophy of the muscular walls with some round cell infiltration. Cultures made from the specimen removed yielded a growth of *Staphylococcus aureus*."

It would seem significant that following the removal of this segment of diseased artery the temperature became normal and remained so until the patient left the hospital a week later. About one week after leaving the hospital there was a recurrence of fever but no local symptoms. The patient returned to the hospital on May 13 for examination. She had gained considerably in strength and her general appearance was much improved. She had had no fever after the first week. The incision over the right temporal artery was healed. The left temporal artery was smaller although it still showed evidence of inflammation. Pulsation was absent. There were no subcutaneous nodules, the eyegrounds were normal and the spleen not palpable. The remaining physical findings were the same as on the first admittance. The blood count had not changed and several specimens of urine were normal. The electrocardio-

FIG 3 Showing multinucleated giant cell formation in adventitial tissue inflammatory reaction

gram was essentially normal. The blood pressure was 166 systolic and 86 diastolic. There was considerable pulsation in the suprasternal notch. A rather extensive pocket was found about one tooth and culture yielded *Streptococcus viridans*. The temperature ranged from normal to 99.6° and the pulse rate from 90 to 130. After dental extractions the patient left the hospital on May 17, 1935. She was seen again August 6, 1935, at which time she stated she felt very well in every way. The blood pressure was 160 systolic and 110 diastolic. The left temporal vessel appeared normal and there was a normal pulsation present. At this time there appeared to be increasing narrowing of the retinal vessels and more pulsation in the suprasternal notch. Our impression at this time was that she presented evidence of a mildly progressive vascular sclerosis. Examination in June 1936 revealed essentially the same findings as the year before. No local recurrence was noted.

In making a final diagnosis in this case one must consider periarteritis nodosa and a localized periarteritis as described by Brown. The clinical course and the histologic picture do not appear to closely simulate periarteritis nodosa. The description of this generalized arterial disease as given in the writings of Kussmaul,² Gruber,³ Rothstein,⁴ Wiener,⁵ Lindberg,⁶ Singer,⁷ Friedberg and Gross,⁸ Curtis and Coffey,⁹ Hausei,¹⁰ Barnard and Burbury,¹¹ Manges and Baehr,¹² and others is that of a widespread involvement of the smaller vessels of the kidneys, heart, lungs, pancreas, mesentery, nerves, muscles and subcutaneous tissues. Since our patient presented no symptoms which might lead one to think of a generalized involvement we were more interested in those cases of arterial disease which presented subcutaneous lesions. Herlitz¹³ reported superficial

FIG 4 Showing the small round cell diffuse infiltration of media and adventitia, also fibroblastic cell reaction

nodules in 12.5 per cent of his cases of periarteritis nodosa. Lindberg⁶ presented in detail a case of a young girl who apparently recovered after several exacerbations of joint pains, fever, anemia and numerous subcutaneous nodules which on section proved to be typical examples of periarteritis nodosa. He also reviewed 20 cases from the literature all being very similar in clinical and pathological detail. We could find no resemblance to our case in any of these

CONCLUSION

A case is presented of localized arterial disease involving the temporal arteries which appears to be separate and distinct from the generalized condition of periarteritis nodosa.

EDITORIALS

THE MEETING AT ST LOUIS

THE Twenty-first Annual Session of the American College of Physicians at St. Louis was in every way a very successful meeting. The total registration, 2,321, places it as the second in size of attendance among all gatherings of the College up to this time. This figure has been surpassed only at the Philadelphia meeting in 1933 where 2,444 were registered. Moreover it was noteworthy that a very large proportion of those in attendance remained until the closing day.

Of the Regents of the College 21 out of 23 were present, and 49 of the 57 Governors either attended or sent representatives.

Throughout the meeting the large hall which housed the General Sessions was almost completely filled each afternoon. The Morning Lectures also drew a large attendance. The Round Table Discussions at the noon hour were an innovation in the program this year. They proved a most popular feature, more than four times the available number of tickets were applied for.

The clinical program provided by the hospitals and medical schools was of an unusually even grade of excellence. Seldom has more enthusiasm been expressed by the members than was brought out in discussions of these carefully arranged clinical meetings. They remain in the minds of the majority the most valuable single feature of our annual session.

St. Louis through its medical representatives greeted the College with warm and gracious hospitality and spared no pains in careful preparation for our reception. All who attended will look back with pleasure upon the days spent in the care of such thoughtful hosts and will hope that they will feel repaid by the gratitude of our members and the manifest success of their undertaking.

THE ANNIVERSARY VOLUME IN HONOR OF DR JOSEPH HERSEY PRATT

IN this number of the *ANNALS OF INTERNAL MEDICINE* there appears a group of articles surmounted by a heading which indicates that they are contributed as the writers' part of an Anniversary Volume in honor of Dr. Joseph Hersey Pratt.

Dr. Joseph Hersey Pratt of Boston, who is widely known among the medical men of this country, will reach his sixty-fifth birthday this year. It was the desire of a large number of his friends to honor this occasion by the presentation to him of an Anniversary Volume. It was his own wish that the valuable contributions to be made to this volume should not be

barred from publication elsewhere as well, in a journal which would ensure their accessibility to the general medical public

By agreement with the Committee in charge of the Anniversary Volume the Annals will publish in the coming months such articles contributed as are judged by the Editor to fall within the field of this journal. This plan, it is felt, will bring before our readers many interesting papers and will at the same time increase the permanent value of these contributions. It is an added pleasure to the Board of Editors that through this arrangement the ANNALS is of service to those who are responsible for this signal honor to an eminent physician

REVIEWS

Urological Roentgenology By MILEY B WESSON, M D, and HOWARD E RUGGLES, M D 269 pages, 24 × 15.5 cm Lea and Febiger, Philadelphia, Pa 1936 Price, \$5.00

Urological Roentgenology is a small volume "prepared to meet the needs of the physician who wants to learn to interpret urograms" It is a 269 page book with 227 engravings There are interesting chapters dealing with the history of urography and its detailed technic in the beginning, while the rest of the book is devoted to the diagnosis and interpretation of urograms covering the entire urogenital tract The illustrations are excellent and not only useful, but essential in arriving at diagnoses of conditions in this tract

Intravenous pyelography is discussed and depicted, its value and limitations are brought out carefully in contra-distinction to retrograde pyelography Some very unusual pyelo-ureterograms of anomalies are shown indicating how easy it is for abnormal organs to undergo pathological changes Also how essential it is to know the exact status of the upper urinary tract before surgery is undertaken, for example, it is necessary to know that there are *two* kidneys before removing *one*

The usual pathological conditions of the kidney are well shown by pyelograms with descriptive footnotes Many of the rare conditions, such as echinococcal cysts and actinomycosis of the kidney are also included

The chapter on traumatism of the urinary tract suggests helpful methods by which the extent of the injury as well as the part of the urinary tract involved may be determined Neurological lesions involving the urinary tract are also discussed

While this book is of unquestioned merit, still it must be borne in mind that no two pathological conditions of the urinary tract are the same and for this reason no two urograms are the same, so diagnoses of urograms may be extremely difficult of interpretation In other words, urograms must be regarded only as additional diagnostic information and not the sole dependency If the physician regards this volume in this light it should be helpful

W H T

A Hand-Book of Ocular Therapeutics By SANFORD R GIFFORD, M D Second Edition 341 pages, 20.5 × 14 cm Lea and Febiger, Philadelphia, Pa 1937 Price, \$3.75

It is with pleasure that we welcome a second edition of this monograph on Ocular Therapeutics The work has been enlarged from 272 pages to 341 pages Additions have been made in the field of vitamin and food therapy and also in that of the use of the various internal secretion extracts in the field of ophthalmology

The application of the different means of physical therapy and the evolution of their use has also been brought up to date The correction of an error in the table for tuberculin dilutions will be welcomed by those using the book as a guide in this type of work The reviewer feels that an initial dose of 1/50,000 mgs of tuberculin as recommended for treatment of a retinal lesion is far too great and may cause very definite damage in a few very sensitive patients

The author and publishers are to be commended for this excellent work which can be recommended as a guide both for the ophthalmologist and the general man who may be called upon to render service in many eye conditions

C A C

The Clinical Use of Digitalis By DRLW LUTEN, M D, Associate Professor of Clinical Medicine, Washington University School of Medicine Indexed 226 pages, 23.5 × 15.5 cm Charles C Thomas, Springfield, Ill and Baltimore, Md 1936 Price, \$3.50

The more recent explanations of the pharmacological and clinical action of digitalis are presented in this volume. The author emphasizes that the clinical indication for the use of this drug is primarily congestive heart failure, no matter what the heart rhythm may be. He also points out that its continued use tends to prevent subsequent failure in a heart which has failed at one time. It would seem to be of use in preventing failure, when such a state might be assumed to be imminent. The reviewer highly recommends this book to practitioners, especially that part which deals with the clinical use of digitalis. As regards some of the considerations of the mode of action of digitalis, at times the argument seems more specious than convincing.

W S L, JR

A Text-Book of Neuro-Anatomy By ALBERT KUNTZ, M D Second Edition 519 pages, 24 × 16 cm Lea and Febiger, Philadelphia, Pa 1936 Price, \$6.00

This book is a straight-forward presentation of facts in text book form. It avoids discussion of debatable subjects, and bibliographic references are to all intents and purposes completely absent in the text though a short list of collateral subject matter is found at the end of each chapter. With this set up the author has been able to cover an astonishing breadth of field in a medium sized text. Thus phylogeny and embryology are featured as an introduction and the embryology of the brain is further discussed in the section dealing with the brain.

The usual sequence of presentation is followed, consideration of neural histology and morphology preceding the detailed internal structure of the central nervous system. The latter is attacked in the order of spinal cord, brain stem and cerebellum and finally the forebrain. Each subtitle, a e, the cranial nerves, ends with a short, but not too short, summary of the subject.

The subject matter is brought up to date, particularly that featuring Cannon's fundamental contributions to the physiology of the autonomic system. The analysis of the cerebral cortex is clear, concise and convincingly illustrated—an altogether useful presentation. A similar success in dealing with the basal nuclei is conspicuously lacking, one leaves this subject with a scant grasp of the significance of these centers.

The clear and abundant illustrations are enriched by numerous Nissl preparations of nuclear areas, a visual asset all too often neglected in this type of work.

Clinical application of neuro-anatomy is presented through description of a series of representative lesions of the nervous system with an analysis of their significance. The book ends with a concise laboratory manual of the dogfish and human brain. One may term this a useful and practical presentation of a difficult subject.

C L D

The Practitioner's Library of Medicine and Surgery Supervising Editor, GEORGE BLUMER, M A (Yale), M D, F A C P, David P Smith Clinical Professor of Medicine, Yale University School of Medicine, Consulting Physician to the New Haven Hospital *Volume XI Eye, Ear, Nose and Throat* Associate Editors ARTHUR M YUDKIN, M D, Clinical Professor of Ophthalmology, Yale University School of Medicine, and PAUL B MACCREADY, M D, F A C S, Assistant Clinical Professor of Otolaryngology, Yale University School of Medicine Lxvii + 1153 pages, 402 illustrations 25 × 17 cm D Appleton-Century Company, New York 1937 Price, \$10.00 a volume

The eleventh volume of *The Practitioner's Library*, like its predecessors which have been reviewed from time to time in the ANNALS, relates the essential material of certain special phases of Medicine to the experiences of the clinician in his daily practice. Thus it presents those diseases of the *Eye, Ear, Nose and Throat* which the general practitioner may encounter at any time, which he can diagnose, and which, for the most part, can be treated adequately by standard, proved methods and with the means readily available to the physician who has a large and varied group of patients. Diagnosis and treatment are emphasized. When major operative procedures are discussed it is with the thought of giving the practitioner such background material as will make it proper for him to advise his patients as to what may properly be expected from those who are recognized specialists in the field in question. This volume, therefore, presents that material which is more or less constantly needed by every practitioner, and which he must have available if he is to serve his clientele adequately in respect to the affections of the special sense organs and related structures.

To this volume there have been 43 contributors, chosen largely from the younger workers in these special fields. The subject matter is divided into four main parts, with about 385 pages devoted to diseases of the Eye, 275 to the Ear, 250 to the Nose, 125 to the Pharynx and 90 to the Larynx. Numerous, and usually well-chosen, illustrations are utilized throughout. Considering the avowed purpose of the book, it must be questioned whether the space occupied by the many low-power photomicrographs in chapter XVII, dealing with the histopathology of the ear, could not have been used to better advantage otherwise. Although obviously prepared from beautiful specimens, such figures require considerable expert knowledge for their appreciation.

As the reviewer has had occasion to mention in respect to earlier volumes of this series, typographical slips are very few for a first edition. A misspelled word in a running head throughout chapter XLV, will offend the eye of a critic, no matter how kindly disposed he may be. The general press work is excellent, the binding substantial and attractive and the index adequate. It is impossible to evaluate the individual chapters provided by the many contributors, but the work as a whole is a worthy member of this series, and will prove a valuable aid to every practitioner of Medicine.

C V W

Being Born. By MRS FRANCES BRUCE STRAIN, Associate Educational Director, Cincinnati Social Hygiene Society. Cloth Price, \$1.50. Pp 144, with 28 illustrations. New York & London: D Appleton-Century Co., 1937.

This book is written by a mother for her children, and covers all the essentials on the subject of human reproduction. It is written especially for the pre-adolescent boy and girl, and is presented in a very sane and healthy manner. There are twelve chapters and "a list of words and their meanings." Most of the material is in the form of questions and answers, which is the best way of presenting the subject to children.

This book can be highly commended for avoiding the abnormal, which unfortunately is introduced in most books on sex, even for children. A few parents might hesitate to tell their children about coitus, or as Mrs. Strain says "mating is not only a way to start one's family, but is also a way of expressing their love, husbands and wives unite when no baby is to be started," but her discussion of this subject cannot cause offense.

The author has covered almost every question that a normal, questioning and curious youngster might ask. She does not beat about the bush, tells how, why, and where babies come into being. The physician certainly can recommend this book to all parents.

J L McC

COLLEGE NEWS NOTES

NOMINATING COMMITTEE FOR 1937-38

In accordance with Article I, Section 3, of the By-Laws of the American College of Physicians, the President, Dr J H Means, has appointed the following Nominating Committee for 1937-38

Dr Jonathan C Meakins, Montreal, Que , *Chau man*,
Dr James B Herrick, Chicago, Ill ,
Dr Alexander M Burgess, Providence, R I ,
Dr A Comingo Griffith, Kansas City, Mo ,
Dr William R Houston, Austin, Tex

The first two names are appointments from the Board of Regents, the second two names are appointments from the Board of Governors, the last name is an appointment from the Fellowship at large

NEW LIFE MEMBER

Dr Estella G Norman (Fellow), Miami Springs, Florida, became a Life Fellow of the American College of Physicians on April 27, 1937

Books

Dr James H Means (Fellow), Boston, Mass , "The Thyroid and its Diseases",
Dr Ralph Pemberton (Fellow), Philadelphia, Pa , "Arthritis and Rheumatoid Conditions",
Dr William R Houston (Fellow), Austin, Tex , "The Art of Treatment",
Dr William Gerry Morgan (Fellow), Washington, D C , "Functional Disorders of the Gastro-intestinal Tract"

REPRINTS

Dr H Sheridan Baketel (Fellow), Jersey City, N J —1 reprint,
Dr Grafton Tyler Brown (Fellow), Washington, D C —1 reprint,
Dr C T Burnett (Fellow), Denver, Colo —15 reprints,
Dr A Morris Ginsberg (Fellow), Kansas City, Mo —1 reprint,
Dr Jacob Gutman (Fellow), Brooklyn, N Y —1 copy, tenth supplement to "Modern Drug Encyclopedia",
Dr Arthur M Master (Fellow), New York, N Y —2 reprints,
Dr Sydney R Miller (Fellow), Baltimore, Md —1 reprint,
Dr Kenneth Phillips (Fellow), Miami, Fla —1 reprint,
Dr William R Rawls (Fellow), New York, N Y —1 reprint,
Dr Paul H Ringer (Fellow), Asheville, N C —1 reprint,
Dr Felix J Underwood (Fellow), Jackson, Miss —1 reprint,
Dr L B Carruthers (Associate), Miraj, India —1 reprint ,
Dr George B Dorff (Associate), Brooklyn, N Y —8 reprints,
Dr Stuart L Vaughan (Associate), Buffalo, N Y —1 reprint,
Dr Walter A Bastedo (Fellow), New York, N Y —3 reprints,
Dr A B Brower (Fellow), Dayton, Ohio —1 reprint,
Dr A Allen Goldbloom (Fellow), New York, N Y —2 reprints,
Dr Charles H Lutterloh (Fellow), Hot Springs, Ark —2 reprints,
Dr Philip B Matz (Fellow), Washington, D C —1 reprint,
Dr Oliver T Osborne (Fellow), New Haven, Conn —1 reprint,

Dr Joseph F Painton (Fellow), Buffalo, N Y—5 reprints,
 Dr Paul A Draper (Associate), Colorado Springs, Colo—2 reprints

MEETING OF SOUTHERN CALIFORNIA MEMBERS

Seventy-five of the Southern California members of the College held a dinner meeting at the California Club, Los Angeles, on March twentieth, 1937 Dr Egerton L Crispin, former Governor and present Regent of the College, presided Dr F M Pottenger, ex-president, spoke upon the certification of internists and other matters pertinent to the College, Dr Wm J Kerr, San Francisco, now president-elect of the College, delivered an interesting address upon the future of the College in the advancement of medicine

TESTIMONIAL DINNER TO DR RIESMAN

Dr David Riesman (Fellow) was guest of honor at a dinner on the evening of March 25, 1937, at the Bellevue-Stratford Hotel, Philadelphia, attended by more than two hundred and fifty of his professional friends on the occasion of his seventieth birthday Guest speakers included Provost Josiah Penniman of the University of Pennsylvania, Dr Alfred Stengel (Master), Dr Henry A Christian (Fellow) of Boston, Dr Lewis A Conner (Fellow) of New York City, Dr Wilmer Krusen of the Philadelphia College of Pharmacy and Science, Dr Wm Gerry Morgan (Fellow) of Washington, and Dr Walter C Alvarez (Fellow) of Rochester, Minn Dr Russell Boles (Fellow) of Philadelphia was toastmaster Dr Stanley C Harris announced that friends of Dr Riesman had made possible the publication of a volume of his selected writings to celebrate his birthday An engraved plate, bearing the names of Dr Riesman's former and present assistants, was presented by Dr Thomas Fitz-Hugh, Jr (Fellow) Dr Riesman responded with a characteristically delightful account of his medical career and of his view of the present and future of medicine envisioned from the vantage point of his "seventy-year-high mountain top"

Dr Albert E Russell (Fellow), U S Public Health Service, Washington, D C, gave the Second Annual Harold S Boquist Memorial Lecture at the University of Minnesota Medical School, Minneapolis, on December 6, 1936

The Annual Meeting of the California Tuberculosis Association was held at Riverside, California, April 1-3, 1937 Dr R H Sundberg (Fellow), San Diego, was chairman of the program committee, Dr F M Pottenger (Fellow), Monrovia, was vice president, Dr Chesley Bush (Fellow), Livermore, Dr R L Cunningham (Fellow), Los Angeles, and Dr W C Voorsanger (Fellow), San Francisco, were directors of the Association Dr Sidney J Shipman (Fellow), San Francisco, acted as chairman of one of the clinical sections, and discussed the paper on bronchial stenosis Dr Robert A Peers (Fellow), Colfax, presented a paper on "Routine Tuberculin Testing in Schools The Part Played by the Medical Profession", Dr Lvell C Kinney (Fellow), San Diego, presented a paper on "Diagnosis of Tuberculosis of the Intestinal Tract", Dr Munford Smith (Fellow), Los Angeles, presented a paper on "Relationship of Trauma to Tuberculosis," said paper being discussed by Dr Philip H Pierson (Fellow), San Francisco, and Dr R L Cunningham (Fellow), Los Angeles, Dr Carl R Howson (Fellow), Los Angeles, presented a paper on "Differential Diagnosis of Diseases of the Chest," said paper being discussed by Dr Munford Smith (Fellow), Los Angeles, and Dr Harold G Trimble

(Fellow), Oakland, Dr Harold G Trimble (Fellow), Oakland, with Dr B H Wardrip, presented a paper on "Pneumoperitoneum—Its Use in Pulmonary Tuberculosis," said paper being discussed by Dr E W Hayes (Fellow), Monrovia, Dr Philip H Pierson (Fellow), San Francisco, discussed the paper on "Simultaneous Bilateral Pneumothorax in the Treatment of Pulmonary Tuberculosis"

The Tenth Annual Graduate Fortnight of the New York Academy of Medicine will be held November 1-12, 1937, and will be devoted to a consideration of medical and surgical disorders of the urinary tract. The subject will include Bright's disease, arterial hypertension, and infections, tumors, calculi and obstructions of the urinary tract, and will exclude venereal disease and gynecology. For the Annual Fortnight a subject of outstanding importance in the practice of medicine and surgery is selected and is presented from as many angles as possible.

The program is under the general direction of the Committee on Medical Education. The following Fellows of the College are members of this Committee: Dr Walter P Anderton, Dr F Warner Bishop, Dr Ralph H Boots, Dr Arthur F Chace, Dr Emanuel Libman, Dr Thomas T Mackie, Dr Herman O Mosenthal, Dr Bernard S Oppenheimer, Dr Maximilian A Ramirez, Dr Willard C Rappleye, Dr Howard F Shattuck, Dr Charles F Tenney and Dr John Wyckoff.

Dr Ralph Pemberton (Fellow), Philadelphia, delivered a series of lectures on "The Modern Outlook upon Arthritis," including the Hartford (Conn.) Medical Society on April 5, the Lycoming County (Pa.) Medical Society at Williamsport, Pa., on April 9, and the New Castle County (Del.) Medical Society at Wilmington, Del., on April 20. Dr Pemberton also addressed the Health Institute sponsored by the Women's Auxiliary of the Philadelphia County Medical Society on April 13 on "Arthritis, and the Problem of Control."

Dr Anthony C Cipollaro (Associate), New York City, has been recently appointed consulting dermatologist at the St. Joseph's Hospital of Far Rockaway.

OBITUARIES

DR CHARLES VINCENT NIEMEYER

Dr Charles Vincent Niemeyer, Fellow, 4610 Hudson Boulevard, Union City, N J, died January 11, 1937, of myocarditis following a collapse in his office six weeks before, at the age of 48

Dr Niemeyer, the son of Carl H and Katherine Niemeyer, was born in New York City, March 7, 1888. He attended public and private school in New York City, and graduated from the University of Vermont, M D, 1912. He served as Intern in Red Cross and St Vincent's Hospital and five years in St Mary's Children Clinic in New York City. In 1914 he moved to Union City, N J, where he began the practice of his profession. In the same year he began the first Baby Welfare Station in North Hudson County and established seven Baby Stations in Monmouth County in 1919. He limited his practice to Pediatrics in 1917, being the first in North Hudson County to do so.

In 1929-32 he did post-graduate work in Vienna, Berlin, London, Mt Sinai of New York, Boston and Chicago.

Rejected during the World War, he organized a Red Cross Chapter for North Hudson and devoted much effort to it. He was a Charter Member of North Hudson Physician's Society, acting as President for one term and as Secretary for fifteen years. He was a member of Osler Medical Society, Hudson County Medical Society, New York Academy of Medicine, New Jersey State Medical Society, American Pediatric Society, American Medical Association, and a Fellow of the American College of Physicians since 1931.

At the time of his death, he was Chief of the Pediatric Staff, St Mary's Hospital, Hoboken, N J, Consultant to St Mary's Hospital and Attending Physician to North Hudson Hospital, Consultant to Christ's Hospital, Jersey City, and to Nyack General Hospital.

He was a member of St Augustine Church, Fourth Degree Knight of Columbus, member of the Newman Club, Kiwanis Club and the Nu Sigma Nu Medical Fraternity. In 1920 he married Caroline Salenius, who survives him.

In so short a span of life, he accomplished much. The Community and the Profession have suffered a great loss in his untimely death.

CLARENCE L ANDREWS, M D, F A C P,
Governor for New Jersey

DR WILLIAM LAFAYETTE RICH

Dr William Lafayette Rich (Fellow), Salt Lake City, Utah, died November 17, 1936, of chronic myocarditis, aged, fifty-eight years.

Dr Rich was born June 17, 1878, at Montpelier, Idaho, and for a number of years had followed the specialty of dermatology. He attended the

Weber State Academy, Ogden, Utah, and the Bear Lake Academy, Paris, Idaho, and later, the Utah Agricultural College at Logan, Utah. He was graduated from Washington University School of Medicine, St. Louis, in 1907, and was certified by the American Board of Dermatology, June 11, 1934. He had pursued postgraduate study at the London Hospital Medical College (University of London), Middlesex Hospital, London, Charing Cross, St. Barth, St. Mary's and other London institutions. In addition, he did postgraduate work at the Vanderbilt Clinic, New York City, and at the New York Postgraduate Medical School.

For several years, Dr. Rich had been chief of the Dermatological Clinic, Salt Lake General Hospital, dermatologist, Dr. W. H. Groves Latter-Day Saints Hospital, St. Mark's Hospital, the U. S. Veterans Administration Facility, and the D and R-G and Western Pacific Railway. He was a Captain, Medical Officers Reserve Corps, and during the World War was a member of the National Advisory Board. He was a former president and a former secretary of the Utah State Medical Association, and a member of the House of Delegates of the American Medical Association in 1923. Dr. Rich had been an active and interested Fellow of the American College of Physicians since 1920.

Dr. Rich was one of the best liked physicians by his colleagues in his city. He had always been active in medical society affairs and enjoyed a large consultant practice up to the time of his death. One of his chief characteristics was that he served as a peace maker. He took an active interest in child welfare work. He will be mourned by many patients as well as by his colleagues.

L. E. VIKO, M.D., F.A.C.P.,
Governor for Utah

DR. B. H. FRAYSER

Benjamin Hobson Frayser, born, Buchanan, Va., October 7, 1887, attended public schools of Charlottesville, Va., Cleveland's Private School, Pantops Academy, Va., and the Fiske Military School, Va., three years, Baltimore Medical College (now University of Maryland), M.D., Lincoln Memorial University Medical Department (now University of Tennessee), 1909, Ph.G., University of the South, 1909, Intern, Pottsville (Pa.) Hospital and Chicago Lying-in Hospital, for a time connected with the Soldiers' Home Service Hospitals at Grand Rapids, at Dayton, Ohio, and at Hot Springs, S. D., also Associate Professor of Obstetrics and Instructor in Anatomy, Lincoln Memorial University, also Associate Professor, Pharmacology, University of the South, Resident Physician, Santo Tomas Hospital, Panama City, 1914-15, in 1915 entered U. S. Indian Medical Service and was in charge of health work in San Juan Hospital, Shiprock, N. M., and Government Hospital, Dulce, N. M., until 1920, from July, 1920, Passed Assistant Surgeon (R) in the following U. S. Public Health Service

Hospitals—New Haven, Connecticut, Boston, Mass., Helena, Mont., and Lexington, Ky., at time of death, Senior Medical Officer, in charge of medical and surgical sections, U S Veterans Administration Facility, Lexington, Ky., founder, Pi Delta Pi Secondary School Fraternity, member, Chi Zeta Chi, medical fraternity, Kappa Phi, pharmaceutical fraternity, Sigma Phi Epsilon and Theta Nu Epsilon fraternities, ex-President, the Association of Government Surgeons of the United States, member, American Medical Association, Association of Government Surgeons, Medical Veterans of the World War, National Reconstruction Alliance, Sons of the American Revolution, Veterans of Foreign Wars, Fellow of the American College of Physicians since March 10, 1923, author of several published papers, and former Business Manager of *The Indian Medical News*

The following information has been supplied by Dr Jo M Ferguson of the Veterans Administration, Lexington, Kentucky, who has been closely associated with Dr Frayser since March 16, 1931

"Dr Frayser was very painstaking in his work, always kind and courteous to the patients in his charge, as well as to all of the personnel with whom he was associated. There was not a physician in the hospital better liked or who was more trusted by every one than Dr Frayser. He was always genial and pleasant and willing at all times to do the most he could for his associates. He was never too busy to listen to complaints of patients and employees and to give of his time and the benefit of his training and experience to those in need of aid or advice. He was always loyal to his fellow workers and had the love and admiration of all those with whom he was associated, and his death on March 5, 1937, has been keenly felt by all."

C W DOWDEN, M D,

Governor for Kentucky

DR RANDOLPH L McCALLA

Dr Randolph L McCalla, an Associate of the College, Boise, Idaho, died October 10, 1936, of uremia, aged forty years. He was born and reared in Boise, the son of the late Dr L P McCalla.

Dr McCalla received his A B degree from Georgetown University, Washington, D C, in 1916, then took two years in medicine at Harvard University, and received his degree in medicine from Columbia University College of Physicians and Surgeons in 1920. He was an interne at St Agnes Hospital, Baltimore, 1920-21, and thereafter, successively, assistant in medicine, instructor in medicine, assistant professor in medicine and chief of the medical clinic at the University of California Medical School, 1924-29. He was house officer in the San Francisco Hospital during 1924-25, and resident physician in the University of California Hospital, 1925-27, assistant visiting physician in the same institution, 1925-29, resident physician, Laguna Honda Home, San Francisco, 1927-29. He then went to

Hawaii, where he was physician-in-charge, Lanai Plantation Hospital, 1930-34. He returned to Boise, Idaho, in May, 1936.

Dr. McCalla had been a member of the California Academy of Medicine, the Territorial Medical Society of Hawaii, and the American Medical Association. More recently, he had become a member of the local societies in Idaho. He was elected an Associate of the American College of Physicians during 1934.

He was the author of several published articles, dealing primarily with cardiology. He was a thoroughly capable internist of high integrity, possessed of an excellent medical mind, a credit to himself and to the organizations with which he was connected.

ANNALS OF INTERNAL MEDICINE

VOLUME 10

JUNE, 1937

NUMBER 12

ADDRESS AT THE ANNUAL CONVOCATION OF THE AMERICAN COLLEGE OF PHYSICIANS *

By the President of the College, ERNEST B BRADLEY, F A C P ,
Lexington, Kentucky

It seems impossible that you should have chosen me, even for one year, to be the President of the American College of Physicians. No greater distinction could come to any man engaged in the practice of Internal Medicine. To me the honor is almost overpowering. All preceding presidents, with possibly one exception, have been teachers and professors of medicine, and even the one exception was a nationally known internist, who came from a great medical center. I could not claim such qualifications. To explain my selection I decided that your Board of Regents and the Nominating Committee felt it was time to show real democracy—to recognize one of that numerous class, who have not had medical honors heaped upon them.

Having been a member of your Board of Governors for a number of years and at that time its Chairman, I took the honor as one bestowed, not upon me personally, but as a recognition by the Board of Regents of the high regard in which your Board of Governors is held. Therefore, as a former Governor, I thank you for them.

Former Presidents, the list of whom includes many of the most eminent internists in the United States and Canada, have delivered addresses which have shown remarkable understanding of modern medical problems. They have explained the ramifications of medical trends and have given sound advice to the members of this organization. Some have gone quite deeply into the discussion of modern problems affecting doctors, "socialized medicine," "state medicine," "social security," etc. These economic questions are very important, but they are also very involved. It might be advisable at our next meeting to devote a whole afternoon or evening to such questions alone. I must confess that I feel incapable of dealing with them adequately, nor would I venture to discuss the various medical problems that are agitating

* Presented at the St. Louis meeting of the American College of Physicians, April 19, 1937.

ing us today, so instead of a Presidential Address, I will try to review briefly the progress of the College during my term of office and to point out to you certain aspects that have impressed me as President. This year has taught me in what great esteem our College is held by other organizations, both lay and medical, and to appreciate the opportunities which this body has for the betterment of medical practice in America.

Except for the preparation of the program of the General Sessions, your President is more or less of a figure-head. It is for this reason, no doubt, that the College has done just as well during the past year as in any preceding one. In fact, its achievements may have been somewhat above the average. When I say that the President is a figure-head, I do not mean this too literally. He has a great deal to do. The major credit, however, should go to the Board of Regents and to the Board of Governors, who individually and through their committees give unsparingly of their time and energy. It is this cooperation that makes the duties of the President a pleasure rather than a task.

In summing up the activities of the College, attention is called first to probably our most important department—the business office. It is here that the Executive-Secretary, Mr. E. R. Loveland, with his clerical assistants take care promptly and efficiently of a vast amount of work. This office is perfectly organized and all records are kept in such a way as to be instantly available when needed. There are multitudinous details connected with applications for membership. Every candidate is investigated most carefully with respect to his qualifications, professional, social and ethical. Cards are sent to all of our members who live anywhere near the residence of the candidate, or, if he has recently changed his address, to all members near his former location. All this information is tabulated so well that the work of the Committee on Credentials is lightened as much as possible. In addition to routine business, collection of dues, etc., there is the preparation and publication of the Directory every two years. And every year there is an immense amount of work connected with the Annual Sessions. Obtaining and arranging the commercial exhibits and preparing the program are but a few of the duties that must be performed. It would be impossible for me to enumerate the many activities of our business office, but all are handled promptly, efficiently and with dignity.

In connection with the work of the business office I have mentioned the preparation and publication every other year of the Directory of our members. This is a most valuable book of reference. The last edition and supplement contains, geographically as well as alphabetically arranged, the names of 3600 physicians engaged in internal medicine and allied specialties. With its biographical data it is invaluable in referring patients to other physicians in distant cities. It is becoming more and more appreciated as a most important "Who's Who" in Internal Medicine.

While we are mentioning assets of which we are proud, your attention is called to the Journal which the College owns and controls. Under the

able Editorship of Dr Maurice Pincoffs, the ANNALS OF INTERNAL MEDICINE has shown a growth that is very gratifying. Each year it has increased in size and importance. The current volume for the twelve months will contain at the present rate almost two thousand pages of scientific reading matter, book reviews, editorials and College news. The scientific articles are not published in a haphazard way, but are chosen carefully by the Editorial Board and may be said to represent the best literature devoted entirely to internal medicine in America. There is also cause for satisfaction in knowing that the Annals is now a financial success and is more than self-supporting. In fact, last year it earned a very substantial sum.

These annual clinical sessions affording a renewal of old friendships and an interchange of medical ideas have come to be regarded by those engaged in the practice of Internal Medicine as the outstanding event of the year. Much of the success of this meeting is due to your General Chairman, Dr David P. Barr. Together with his associates on the various committees, he has worked long and faithfully to formulate the program which we are enjoying this week. The Clinics at the Hospitals are an inspiration to us all, and we shall not soon forget the hospitality that has been extended to us here in St. Louis. These people from Missouri do not "Have to be shown" how to make us feel at home. We hope that at some future time they will be willing to let us come back again.

Two projects of importance to the College had their culmination during the past year, both of them having been instigated during the year preceding. I refer, first to the organization of the American Board of Internal Medicine, and second, to the purchase of a permanent headquarters.

Initiated by the American College of Physicians, and with the cooperation of the Section on Medicine of the American Medical Association, the American Board of Internal Medicine completed its organization in June 1936 and is now actively functioning. The purpose of this Board is briefly, the certification of specialists in the field of internal medicine. The growth of specialism has called into action many similar Boards of Certification. There are now eleven such boards. They are, in the order of their establishment, the American Boards of, Ophthalmology, Otolaryngology, Obstetrics and Gynecology, Dermatology and Syphilology, Psychiatry and Neurology, Radiology, Orthopedic Surgery, Urology, Internal Medicine, and Pathology. The American Board of Surgery has completed its preliminary steps and is almost ready to function.

The plan of certifying specialists has been one of the developments of modern medicine that has resulted from the enormous growth of specialism itself. Since one could be listed as a specialist by merely claiming to be a specialist, there seemed to be no proper way to distinguish between the qualified and the unqualified. Of course, in many cases, such certification is wholly superfluous. Many specialists by reason of long and successful practice, by their hospital and medical school connections, or by the regard in which they are held by members of the medical profession familiar with

their work, will gain nothing by being certified in any particular specialty. Dr. George H. Meeker, Dean of the Graduate School of Medicine of the University of Pennsylvania has called this "casual" certification, whereas, the evolutionary tendencies in the whole medical field he says are an abandonment of the "casual" for the "systematic." It is this tendency to be more systematic that has caused the growth of these boards of certification. It is evident that certification of internists will result in changes in postgraduate work to provide for more systematic preparation for this specialty. In just what way this will be done is somewhat uncertain. However, it will result probably in a longer training in internal medicine during the years of hospital residence, with more hospitals of approved class offering residencies in medicine. Other changes will no doubt come about, the nature of which cannot be definitely foreseen at this time. In the long run it would seem that certification must result in better preparation before specialism is attempted.

Certain constitutional amendments were proposed at the December meeting of the Board of Regents and have been published in the ANNALS. They would have caused very drastic changes in the selection of new members. The first change was in Article IV, which states that "Fellows shall be members of the medical profession, engaged as practitioners, teachers or research workers in Internal Medicine or in an allied specialty, etc." It was proposed to leave out the phrase, "or in an allied specialty," thus restricting future membership to those engaged in Internal Medicine alone. It was also proposed to make the successful passage of the examination for certification a pre-requisite for Associateship. These changes if adopted, while in no way affecting our present membership, would have influenced materially the future selection of Associates and Fellows. At the meeting of the Board of Regents last Sunday it was decided not to take up consideration of these amendments at this time.

It is apparent that Fellowship in the College will mean much more than mere Certification, which is only one qualification that must be met, just as it is necessary now that the candidate be a graduate of an approved medical school and must hold membership in his county, state and national medical organizations. These are preliminary requirements. Many other qualifications for Fellowship are now considered by the Committee on Credentials, and as time goes on Fellowship will become more difficult and therefore more desirable than in the past.

Two years ago it seemed apparent to the Officers and Regents of our College that a Board for the Certification of Internists would be formed, and it was felt that if such were the case the American College of Physicians should exercise control over it. Since the American Board of Ophthalmology was formed twenty-four years ago and eight other boards were organized prior to the American Board of Internal Medicine, it must be evident that this procedure was not entered into hastily. The personnel of the American Board of Internal Medicine is a sufficient guarantee of its

successful administration The College owes a great debt to the Chairman and members of this Board for the time and energy which they have spent in this very complicated organization The Chairman, Dr Walter L Bierring, will discuss more fully the workings of this Board at the General Sessions

The other most interesting achievement of the College during the past year was the purchase of a building in Philadelphia as a permanent home Encouraged by my predecessor, Dr James Alexander Miller, the pioneer work on this project was done by Dr Alfred Stengel prior to our meeting in Detroit last year Their arguments convinced the Boards of Regents and Governors that the College should own a suitable headquarters building It no longer seemed appropriate that an organization of our size and importance should occupy rented rooms in an office building Accordingly, a Committee on College Headquarters was appointed, which after much investigation, advised the purchase of a fine old residence in Philadelphia This purchase was consummated during the past summer, a few necessary alterations were made and the house was furnished in time for the December meeting of the Board of Regents The thanks of the College for the selection of the property and for the successful completion of this project should be tendered to this committee, of which Dr O H Perry Pepper was Chairman Fortunately for us, large city houses of this sort are not in great demand, so that the College was able to acquire a very handsome and expensive property at very little more than the value of the lot upon which it stands It is situated on the corner of Pine and Forty-Second Streets in Philadelphia in a neighborhood that apparently will not soon deteriorate The house is a three-story brick residence, dignified in appearance, and is surrounded by a large yard with beautiful planting The whole property is enclosed by a high iron fence which adds much to its appearance The advantages of this acquisition are that the executive offices now have abundant space, there are rooms for the meetings of the Board of Regents and their committees, further expansion is provided for when it becomes necessary, and the College has a home of its own of which I am sure you will be proud All members are urged to visit the new headquarters when in Philadelphia

One of the encouraging features of the past year has been the increased interest shown in Life Memberships As you know, the revenue from this source goes into the endowment fund, the income from which is used solely to further the scientific purposes of the College In the year just closed 18 Fellows have shown concretely that they appreciate this aim of the College We now have a total of 79 Life Members and about \$62,000 00 in this fund

Numerically, the membership of the College has shown a healthy growth during the year One hundred and seventy-two have been elected to Fellowship and 276 to Associateship On the roster of the College at the present time there are 2 Masters, 2684 Fellows and 998 Associates, a total of 3684

This is a large number and results in such a big attendance at these Annual Sessions that only the largest cities can adequately care for them. However, with the standards for membership being constantly made more rigid, the growth of the College will necessarily be much slower from this time forward, and from a practical standpoint this is not an unmixed evil. The meetings would lose much if they should have to be divided into Regional Assemblies, as is done by another of our national societies.

Detracting in no way from these Annual Sessions have been the state meetings which have shown a remarkable increase in the past two years due to the efforts of our Governors. These state meetings have been more or less social. Some have been held at the time and place of the meeting of the State Medical Society, while others have convened at some central city with or without a scientific program. It has been my good fortune during the past year to attend several of these state gatherings, and at all of them, those in attendance seemed enthusiastic and voted to continue these meetings annually.

After discussing the growth of the College, it is fitting that we now take account of our losses since our last meeting. For failure to pay dues or by resignation we have lost only 10 Fellows and 10 Associates. Death, however, has not been so kind. Two Masters, 52 Fellows and 4 Associates have passed to the "great beyond." Included in this list were some of our most active and distinguished members. Time will permit me to refer to only a few—Henry F. Stoll and Ernest E. Laubaugh, Governors for the States of Connecticut and Idaho respectively, and Luther F. Warren of Brooklyn, a member of the Board of Regents, were actively engaged in the affairs of the College and will be sorely missed. W. McKim Marriott and Henry S. Plummer were former members of the Board of Regents. Both of these men were known personally or by reputation to all of you. Dr. Marriott, as you know, had recently removed from this city to San Francisco. Dr. Plummer's work at the Mayo Clinic is equally well-known to you. It would be futile for me to enumerate the professional attainments of these eminent physicians. Their work is familiar to the whole medical world.

We mourn also tonight three past presidents, James M. Anders, Harlow Brooks and Frank Smithies. James M. Anders, called the "Nestor of the Philadelphia Medical Profession," "A Gentleman of the Old School," was President of the College in 1922 to 1923 and was the first to be honored with the title of "Master of the American College of Physicians." He was known to all internists in America, and was the author of many medical works. He maintained a lively interest in this society until the time of his death.

Harlow Brooks of New York, was President for the two years succeeding Dr. Anders, 1923 to 1925 and was a member of the Board of Regents for a number of years. He became a Fellow in 1916 at the first regular

meeting of the College and also served as Governor of the College for New York from 1929 to 1931. He has been called the "Doctor's Doctor," had a nation-wide reputation as a diagnostician and was widely sought as a consultant. He was loved by all who knew him well.

Frank Smithies, whose death occurred rather suddenly early in February, deserves especial mention. If it had not been for Frank Smithies there might not have been an American College of Physicians, at any rate, he had much to do with its formation. During its early years *he* was the College. He arranged the places of meeting, made out the programs and carried on practically all the business of the College. He was the founder of our Journal. He was Secretary-General from 1922 to 1926 and President 1927 to 1928. In recognition of his work he was made a "Master." Frank Smithies had great personality, he possessed an almost unbelievable capacity for hard work, which in spite of physical handicaps enabled him to win distinction and many honors in the field of American Medicine. In the passing of James M. Anders, Harlow Brooks and Frank Smithies, the College has lost three of its pioneers, who served it in its infancy.

The College is an infant no longer. This year marks the twenty-first Annual Sessions, so that now it may be said to be grown to manhood, and like a young man, it is strong, virile, optimistic and progressive. During these twenty-one years it has gradually attained all the objectives for which these pioneer founders had hoped. The Annual Sessions still remain its most important accomplishment, but other activities, most of which I have mentioned, are hardly less valuable. Through the establishment of the John Phillips Memorial Award and the giving of Fellowships to assist in research work, it recognizes and aids the efforts of earnest students of medicine. It owns and publishes a great medical journal. Furthermore, it is supervising the classification and certification of Internists. And it now owns a permanent home. These results, while gratifying, are not enough. We must not allow ourselves to become satisfied. Dr. Aldred Scott Warthin pointed out in an Editorial a short time before his death, that the College must develop its cultural side and take advantage of its opportunities to influence and guide medical thought in the country. I feel that now, given the right kind of leadership, with our strong organization, the College may look forward to the future with eagerness and confidence, and that it will do its part toward the forming of medical ideals throughout America.

THE AMERICAN BOARD OF INTERNAL MEDICINE *

By WALTER L. BIERRING, M.D., F.A.C.P., Chairman, *Des Moines, Iowa*

THE growth of specialism in America is in line with progress, and significant of the remarkable advancement of knowledge in every field of medicine since the opening of the century.

That modern diagnostic technic is based on special training is obvious, and its influence towards specialized medical and surgical practice is likewise apparent.

In the evolution of American medical schools during the past three decades, uniformity of curriculum and hours of study constituted all too frequently the principal standard of measurement, and in consequence, courses in certain specialties occupied a large part of the undergraduate curriculum.

This was reflected in the increasing number of medical graduates taking up one or the other of the specialties, directly upon admission to practice. The studies of Weiskotten indicated that an average of 10 per cent of recent graduates entered the field of specialized practice in 1910, and this rose to the unusual figure of 35 per cent in 1930. This state of affairs became a matter of considerable concern to medical educators, and the profession generally recognized the inherent dangers of this large influx of incompletely prepared specialists in the different fields.

With the advent of special certification, the training of specialists is definitely within the field of postgraduate medical education.

In certain of the European countries legal provisions control the licensure of specialists, but such measures did not seem practicable for this country. In the many discussions on the subject, the consensus was that the responsibility lay on the organized medical profession as represented by the American Medical Association, and that any form of legislative control was undesirable.

It is to the credit of special societies in two specialties, ophthalmology and otolaryngology, that they have taken the initiative and led the way towards the formation of qualifying and certifying boards in the different medical specialties.

The American Board of Ophthalmology was the pioneer in this field, being organized in 1916, and has been certifying specialists in ophthalmology ever since. The American Board of Otolaryngology was formed in 1923, the American Board of Obstetrics and Gynecology in 1927, and the American Board of Dermatology and Syphilology in 1929.

As other specialties began to take steps towards forming similar qualifying boards, the need was recognized for some central agency or supervising

* Presented at the St. Louis meeting of the American College of Physicians, April 22, 1937.

body such as the Council on Medical Education and Hospitals of the American Medical Association for the purpose of coordinating graduate education and the certification of specialists in the United States and Canada. A further purpose was to formulate standards of administration in general, based upon those of the four specialty boards previously organized, and to recognize new boards meeting those standards.

In order to avoid duplication of effort as well as to coordinate the work of the several boards, and other interested groups, it was deemed advisable to create an Advisory Board for Medical Specialties, which should be representative of each organization concerned. This Advisory Board began to function in February 1934. Since that time the American Board of Pediatrics, the American Board of Neurology and Psychiatry, the American Board of Radiology, the American Board of Orthopedic Surgery, the American Board of Urology, the American Board of Internal Medicine, the American Board of Pathology, and the American Board of Surgery have been formed, thus completing the organization of certifying boards in the twelve recognized medical and surgical specialties.

Each of the twelve specialty boards comprise in their membership representatives from the national special societies concerned and the section of the particular specialty in the Scientific Assembly of the American Medical Association.

The formation of an American Board for the Certification of Internists originated with the action of the Board of Regents of the American College of Physicians at the session in Philadelphia, April 30, 1935, when a resolution was adopted to cooperate with the Section on the Practice of Medicine of the American Medical Association in the appointment of a representative committee of organization.

After fulfilling the necessary requirements to obtain the approval of the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association, the Articles of Incorporation of the American Board of Internal Medicine were filed on the twenty-eighth day of February 1936.

The official organization was completed and the Board began to function on July 1, 1936. The membership of the first Board was composed of the following members: Dr. Jonathan C. Meakins, Montreal, Vice-Chairman, Dr. O. H. Perry Pepper, Philadelphia, Secretary-Treasurer, Dr. David P. Barr, St. Louis, Dr. William S. Middleton, Madison, Wisconsin, and Dr. G. Gill Richards, Salt Lake City, representing the American College of Physicians, and Dr. Ernest E. Irons, Chicago, Dr. Reginald Fitz, Boston, Dr. John H. Musser, New Orleans, and Dr. Walter L. Bierring, Des Moines, Chairman, as representatives of the Section on the Practice of Medicine of the American Medical Association.

The purpose and objective of the Board is the certification of specialists in the field of internal medicine, and the establishment of qualifications for

such certification, and of the procedure necessary for the accomplishment of such objective

In its various announcements, the Board has endeavored not to establish any fixed rules for the preliminary training of candidates for certification in this field, but rather to outline or suggest certain broad general principles for training—subject by necessity, to constant changes reflecting the dynamic nature of the specialty

It is generally recognized that a sound knowledge of physiology, biochemistry, pathology and the other basic sciences, insofar as they apply to disease, is essential for continued progress of the individual who practices internal medicine

A portion of the written examination required for certification is, therefore, designed to test the candidates' knowledge of these "pre-clinical" subjects and especially in their application to disease rather than their purely laboratory aspects

The mere factual knowledge of medicine and its basic sciences is not sufficient. The candidate must have had training in their use in furthering his understanding in clinical medicine. This implies practical experience under the guidance of older men who bring to their clinical problems ripe knowledge and critical judgment. Preparation to meet this requirement adequately may be even more difficult to obtain than the so-called scientific training. It may, however, be acquired in the following ways

- A By work in a well-organized hospital out-door clinic conducted by competent physicians
- B By a prolonged period of resident hospital appointments, likewise directed by skilled physicians
- C By a period of training in intimate association with a well-trained and critical physician who takes the trouble to teach and guide his assistant rather than to expect him only to carry out the minor drudgery of a busy practice

The Board does not consider it to the best interests of internal medicine in this country that rigid rules as to where or how the training outlined above is to be obtained. Medical teaching and knowledge are international. The opportunities of all prospective candidates are not the same. Some may have the opportunity of widening their knowledge by a period of study abroad. Others, at the other extreme, may be restricted to a comparatively narrow geographic area and their more detailed training must be obtained in short periods scattered over a longer period of time. Although it is required that at least five years must elapse between the termination of the first intern year and the date when the candidate is eligible to take the examination, a longer period is advisable. The Board wishes to emphasize that time and training are but a means to the end of acquiring a breadth and depth of knowledge of internal medicine which the candidate must demonstrate to the Board in order to justify it in certifying that he is competent to

practice internal medicine as a specialty. The responsibility of acquiring the knowledge as best he may rests with the candidate, while the responsibility of maintaining the standard of knowledge required for certification devolves on the Board.

The examination required of candidates for certification as specialists in internal medicine will consist of Part I (written), and Part II (practical or clinical).

Part I. The written examination is to be held simultaneously in different sections of the United States and Canada and will include

- A. Questions in applied physiology, anatomy, physiological chemistry, pathology, bacteriology, and pharmacology as related to internal medicine as well as the cultural aspects of medicine.
- B. Questions in general internal medicine.

Part II. Candidates successful in the written tests will be eligible for the practical or clinical examination, which will be conducted by the members of the Board near the time and place of the annual meeting of the American College of Physicians and of the American Medical Association.

Two written examinations have been held, with fifty (50) candidates appearing for the examination on December 14, 1936 and thirty-six (36) on March 22, 1937.

The first practical examination will be conducted by members of the Board at the City Hospital, St. Louis, on April 23, 1937, at which thirty-five (35) candidates are expected to appear. A second practical examination will be conducted in Philadelphia on June 5, 1937. The next written test will be held in different centers in October 1937 and a practical examination will be held in Chicago in February 1937.

CERTIFICATION WITHOUT EXAMINATION

The organization, during the past forty years, of seven special societies concerned mainly with the advancement of internal medicine is significant of the leadership that has been attained in this specialized form of medical practice.

The desire to maintain these high standards of internal medicine has been a potent influence in developing the present plan of certification procedure.

In inaugurating this movement it seemed fitting to consider the special recognition of leading internists in the United States and Canada, who as teachers or through experience in specialized practice had distinctly contributed to the advancement of internal medicine.

It was therefore decided to consider applications for certification without examination from the following three groups:

- 1 Professors and associate professors of medicine in approved medical schools in United States and Canada
- 2 Members or Fellows in good standing in the following special societies, who had limited their practice to the specialty of internal medicine for ten years or longer
 - A* Association of American Physicians
 - B* American College of Physicians
 - C* Royal College of Physicians of Canada
 - D* American Clinical and Climatological Association
 - E* American Gastro-Enterological Association
 - F* American Society for Clinical Investigation
 - G* Central Society for Clinical Research
- 3 Licensed physicians who had limited their practice to the specialty of internal medicine for fifteen (15) years or longer and were recommended for certification by the Executive Committee of the Section on the Practice of Medicine of the American Medical Association

During the year more than one thousand (1000) of such applications have been received and the proper evaluation of the eligibility of each applicant has proved a more difficult problem than at first anticipated. As several months will probably transpire before final announcement can be made, the Board trusts that it may enlist the charity and patience of all those who are concerned.

The certification of the more limited specialties of internal medicine such as cardiology, gastro-enterology, allergy, tuberculosis, etc., has been given very careful consideration by the Board since its organization.

In an earlier announcement the Board published the intention to inaugurate, immediately after July 1, 1937, qualification and procedure similar to that in general internal medicine, for additional certification in the above named restricted and specialized branches.

In view of the various problems that have developed during the period of organization and institution of the general plan of certifying procedure, the Board considers that it would be more practical to defer this additional certification for the present or until the plan of certification of specialists in the general field of internal medicine is more completely established.

The general approval that has been accorded the American Board of Internal Medicine in its efforts to institute the aims and purposes for which it was organized has been most gratifying. The Board takes this opportunity to express its obligation to the Officers, Regents, Governors and Fellows of the American College of Physicians, as well as to the members of the Executive Committee of the Section on the Practice of Medicine of the American Medical Association and the officers of the several special societies of internal medicine for valuable advice and counsel extended at all times.

The Board trusts that it can continue to count on this cooperation, particularly in directing the younger physicians in courses of special training with certification in internal medicine as the objective

It will be evident that the standard of qualifications for election to Fellowship in the American College of Physicians and in other special societies of internal medicine will be distinctly influenced by such certification

The Board is, likewise, firmly convinced that the simple procedure of certification is of minor import as compared with the effect this movement will have in elevating the standards of medical specialists, in advancing the development of postgraduate medical education, particularly the thorough training in internal medicine, and ultimately in benefiting the patient who is at all times entitled to the highest type of medical service

RHEUMATIC HEART DISEASE IN PHILADELPHIA SCHOOL CHILDREN¹

By JACOB M. CAHAN, M.D., F.A.C.P., *Philadelphia, Pennsylvania*

ABOUT 1 per cent of the 350,000 children in the public and parochial schools of Philadelphia[†] have some form of heart disease. The main causes of heart affection, as is well known, are congenital developmental defects, rheumatic fever and other infections, syphilis and degenerative changes. Of these causes, congenital defects and rheumatic infection, chiefly, pertain to children of school age, and rheumatic heart disease by itself constitutes by far the most frequent variety. The common age at the onset of rheumatic infection coincides with the years of the child's school attendance, namely, from five to eighteen. In fact, the child is most susceptible to rheumatic infection during the first four years of school attendance. The opportunity to study the earliest phenomena of the greatest cause of heart disease in children thus presents itself to the medical supervisor of the pupils' health.

PROSPECTUS OF THE REPORT

Briefly outlined, this report contains the following:

- 1 Inferences that can be drawn from the histories of juvenile rheumatic infection
- 2 Prevalence of various infections in the children studied
- 3 The incidence of abnormal hearts
- 4 The incidence of recognizable congenital and rheumatic heart disease
- 5 Classification and description of restrictions of physical activities in public schools
- 6 Correlation of the functional capacity of the cardiac patient with the restricted physical activities
- 7 Diagnostic aids in determining when the rheumatic infection is inactive
- 8 A word as to how safely a child with heart disease can be guided through his school years

PROCEDURE

Eleven public school physicians reviewed the medical record cards[‡] of 33,293 pupils enrolled in one school district, known as District No. 9. These medical records showed the respective school physician's findings at

* Received for publication August 12, 1936.

† Philadelphia, Pennsylvania, is a city of over two million inhabitants, and has a temperate climate. North Philadelphia, the section in which the survey has been conducted, is inhabited largely by families whose social condition is a little better than the average, although about one-fifth of them are poor.

‡ A blank form will be furnished with the reprint, on request.

the annual physical examination of the pupil. Thus, unlike a previous survey¹ based on my own selection, these children have been nominated for study by the 11 medical inspectors in the schools. Of the many items found on a pupil's medical record, the following were selected: name, school, date of birth, sex, race, and grade. In addition, for each pupil a note was made of the date of the physical examination that indicated the abnormal cardiac condition, the diagnosis made or signs discovered on examination of the heart, the severity of the condition, whether the pupil had been indulging in gymnasium work, any other defect that had been discovered, and the identification number of the school physician. A notation was made of every child who had any abnormality marked under the caption of "heart," at any previous examination. Any record of "nervousness" and "chorea" was also noted. Another source of suspected heart cases was found in prolonged absences, recorded with the Compulsory Attendance Department. The Compulsory Department supervises prolonged absences, and enforces attendance. Children who are unable to attend school furnish the school which they should attend with an excuse from their private physician or report from hospital. The Compulsory Department, in the district surveyed, had on file reports on 261 children who had been absent for months or years. Twenty-four of these reports (9 per cent) showed the absences to be due to some circulatory disturbance, and these cases were included in the study. Additional names of suspected heart cases were obtained from the 28 school principals, their secretaries, and the 11 school nurses employed in this district. While there are 10 school districts in the city, the survey covered about one-eighth of the entire public school population, and about one-ninth of all the Philadelphia children of school age.

A preliminary physical examination was the next step. Of the 863 pupils examined the first time, 472 showed no evidence of heart lesion or suspicion of it, and were thus eliminated, and 391 were slated for study. A juvenile rheumatic disease blank was then provided for each case, and the history was obtained from the parent, by a school nurse or physician. For the girls, a special permission was secured to remove "sufficient clothing from the chest and shoulders" to enable the doctor to examine the chest carefully.

The physical examination of the children included mainly the parts of the body bearing on the circulatory system. An attempt was made, however, to investigate any additional points of interest, disclosed in the anamnesis or by signs revealed on examination. In all cases reexaminations were made within the next year, and in many instances a third examination was made this year, 1936.

INFERENCES FROM THE HISTORIES

Each summarized history was placed in one of three different classes, depending on the amount and nature of evidence of rheumatic infection,

namely "Actual," when acute rheumatic fever, chorea, or other unmistakable history of rheumatic infection was present, "Suspicious," when there was no convincing proof of actual infection, and "Negative," when there was no past or present evidence of rheumatic affection. A tabulation of all items in these histories showed tens of thousands of entries, a discussion of which would be too lengthy. Nor is it necessary. A brief comment on some of the more interesting points will suffice.

The particular school population of 33,293 pupils surveyed contained 157 children of the negro race, but of the 391 cases studied, only one was colored. Of these 391 studied cases, 214 were boys and 177 girls. Three hundred and fifty of the 391 studied showed abnormalities, either in the history or on physical examination, or in both. Of these 350 (1.1 per cent of entire school population reviewed), 191 (0.6 per cent) showed signs of organic heart disease, later to be described, 113 (0.33 per cent) pupils were recorded as showing "Abnormal signs or symptoms referable to the heart but the diagnosis of heart disease uncertain" (Class E), and 46 (0.013 per cent) were classed as children "Without circulatory disease whom it is advisable to follow because of the presence or history of an etiological factor which might cause heart disease" (Class F). These two classes and their quoted definitions are in compliance with the Standard Classification and Diagnosis of Heart Disease as accepted by the American Heart Association.

Classes E and F should form interesting groups for observation, prolonged if possible, even after the pupils leave the public school. Will they establish their freedom from heart affection, retain their functional heart conditions, or develop organic heart disease? If the last should happen, one would like to know under what circumstances it has occurred, and if it was possible to prevent it.

It is interesting to note that in the final classification eight children with organic heart disease had entirely negative histories as far as any infection allied to juvenile rheumatic disease, or known congenital maldevelopment is concerned. On the other hand, five pupils with actual histories of past rheumatic infection, 45 with suspicious histories, and 63 with negative histories were among those children in Class E. Five children with actual histories, 19 with suspicious histories, and 22 with negative histories belonged to Class F. Thus, it is quite possible that, had histories been obtained on all 863 nominated pupils, and had the 472 children not been entirely eliminated at the first examination that additional children with heart disease would have been discovered. Also, more children might have been found belonging to Class E or F.

In the subsequent discussions of points in the anamnesis, the numbers and percentages refer to the 350 pupils with abnormal hearts. Children belonging to Classes E and F have been included in this discussion.

DISCUSSION OF SOME MANIFESTATIONS

Tonsillitis Of the 140 children (40 per cent) that had tonsillitis, 61 had an occasional attack, 53 had few attacks, 21 had many attacks, and 5 had very many attacks. The total number of children that had tonsillitis at the ages of three, five, and six, was one and one-half times the total number of cases of all the children of all other ages between two and fourteen. In fact, almost one-half of all the children that had tonsillitis had their first attacks at the ages of five and six. Within a year of the first attack of tonsillitis, 43 children had their tonsils removed, and before two years passed, 37 more had the operation. Altogether 101 children who had had tonsillitis subsequently had tonsillectomies, but there were 11 additional children who gave a history of tonsillitis after tonsillectomy. A total of 110 children had no history of tonsillitis yet had tonsillectomies, and only 28 that had had tonsillitis had no tonsillectomies. Of the 65 children that had acute rheumatic fever, 36 had tonsillectomies before the first attack of rheumatic fever, 15 after it, and 14 children had no tonsillectomies. Of the 39 pupils that had chorea, 15 had their first attack before tonsillectomy, 17 had it after the operation, while seven had retained their tonsils. One can infer from these data, among other things, that the popular operation of tonsillectomy is often inadequate to prevent entirely or to ameliorate without fail all cases of chorea, acute rheumatic fever or rheumatic heart disease. Even tonsillitis itself had occurred after some tonsillectomies.

Acute rheumatic fever was present in 18.6 per cent of the histories. More children had their first acute attack of rheumatic fever, *recurrent fever*, and *involuntary twitchings* at the age of seven than at any other age. The number of attacks of rheumatic fever varied from one to five, the last mentioned being in a child whose first attack occurred at seven.

Chorea occurred in 11 per cent. The first attack of chorea occurred in more children at eight years of age than at any other age. At the ages of seven and five the next larger number of children had their first attack.

A greater number of children had their first or only attack of *recurrent unexplained abdominal pains*, *joint pains*, *swelling of joints*, *pain in the region of the heart*, "*heart disease*," and *scarlet fever* at five years than at any other age.

Emmesis occurred for the first time most frequently in children of nine years, *severe muscle* or "*growing pains*," at 10 years of age, and "*heart failure*" at eleven. An equal number of children had their first attack of epistaxis at eight and 12 years of age. The onset of *sinus disease* was noted most frequently in the twelfth year, although it began almost as frequently in the third and sixth years. Dental infection was present in 52 per cent of the children.

Familial Predisposition The insidiousness of the onset of many cases of rheumatic heart disease and the chronicity of the asymptomatic stage of the heart affection make one suspect the possibility of familial incidence of

the disease, as in tuberculosis. This was borne out in this survey. Among the 350 cardiacs 79 (22.6 per cent) had a history either of some near relative having heart affection or of a sibling with rheumatic heart disease. These relatives were as follows: 29 grandparents, 20 mothers, three fathers, both parents (one instance), other relatives (eight instances), nine brothers and nine sisters. Four pairs of siblings were under observation. Unfortunately, it was not ascertained whether among the adults there were some suffering from other than rheumatic heart disease—which was very likely. In view of this incidence of rheumatic heart disease in the family, examination of every available member of the family is advisable, once a member is found to have rheumatic heart disease.

A brief summary of the actual, suspicious and negative histories of the 391 cardiac suspects is shown in the following table.

TABLE I
Prevalence of Conditions in 391 Histories

Conditions in order of prevalence	In children with			Total
	Actual rheumatic history	Suspicious rheumatic history	Negative history	
Measles	80	116	121	317
Pertussis	59	70	76	205
Tonsillitis	44	62	34	140
"Heart disease"	57	54	24	135
Severe muscle or "growing pains"	38	58	16	112
Recurrent common colds	25	37	21	83
Heart pains	33	46	4	83
Chicken pox	27	20	20	67
Acute rheumatic fever	58	7	0	65
Scarlet fever	21	29	10	60
Recurrent unexplained abdominal pains	21	35	2	58
Pneumonia	13	22	20	55
Involuntary twitchings	35	16	4	55
Joint pains	29	24	1	54
Epistaxis	20	16	12	48
Recurrent fever	24	14	3	41
Mumps	18	13	10	41
Chorea	38	1	0	39
Enuresis	10	19	9	38
Diphtheria	8	17	10	35
Influenza	12	15	3	30
Swelling of joints	17	4	1	22
Sinus disease	4	11	6	21
"Heart failure"	8	8	4	20
Nodules under the skin	2	1	0	3

PHYSICAL EXAMINATIONS

Mindful of the inference drawn from the history, each girl as well as boy was examined with bared front of the chest. There were just as many pupils with rheumatic cardiac affection whose general appearance was fair or good as there were of poor appearance. Twenty-one showed choreiform

movements. Pallor and fever were found in a smaller percentage of children examined in school than in those examined at home. Tonsils were present in almost 50 per cent of the children. Two-thirds of the children had enlarged glands in the neck. A pulse rate of over 100 per minute was not found indicative of rheumatic affection, as many children without signs of heart disease also had that rate. The temperatures of a number of children were above 99° F (by mouth). For the sake of brevity, diagnoses will be stated without enumerating the accepted diagnostic signs or criteria. I wish to introduce and discuss, however, a new anatomical landmark used for the anterior chest wall.

A NEW LANDMARK ON THE CHEST WALL

In recording cardiac enlargement I have been in the habit of designating the point midway between the midclavicular and anterior axillary lines as the "preaxillary" line, adding the interspace at which the apex beat was felt. The preaxillary line is an imaginary line on the front of either side of the chest, drawn vertically downward, midway between the midclavicular and anterior axillary lines, and parallel to them. It divides vertically the surface area of the chest wall between the midclavicular and anterior axillary lines exactly in half. Unlike the parasternal line which is similarly drawn from the medial half of the clavicle, the preaxillary line does not take origin from the outer half of the clavicle. Although I do not remember seeing any reference to such an anatomical landmark, I find it more convenient and descriptive than any measured distance from the midclavicular line. The preaxillary line seems to me to have a more constant relation to the person's chest as it is applicable to a patient of any age, size, or stature. Furthermore, one can express the relation of the apex beat to the preaxillary line by stating whether the apex beat is near or beyond this line. The apex beat may be located midway between the midclavicular and preaxillary lines or between the preaxillary and anterior axillary lines. Such a descriptive location of the apex beat seems to make possible a more constant anatomical site of the finding. A given measured distance in centimeters or inches would not be so self-explanatory, for one must know the approximate size of the chest. What is true of the use of the preaxillary line for the apex beat is also true for designating the margin of cardiac dullness, and flatness of pericardial effusion. Less frequently, the preaxillary line on either side may be used to designate the outline of pathologic pulmonary or pleuritic structures, as in extracardiac foreign bodies, consolidations, effusions or neoplasm in the chest.

DIAGNOSES OF HEART DISEASE

A diagnosis of organic heart disease, congenital or acquired, was made in 191 pupils. Briefly, the diagnoses were as follows:

<i>Etiological Diagnosis</i>	No. of Cases
Congenital developmental defect	28
Congenital developmental defect combined with acquired heart disease, rheumatic	2
Rheumatic heart disease, active and inactive	129
Measles	1
Scarlet fever	8
Hypertension	4
Nephritis	1
Unknown (probably rheumatic)	18
Total	191

Anatomical Diagnosis

Congenital cyanotic lesion (tetralogy of Fallot)	4
Congenital acyanotic lesion	24
Hypertrophy of heart, including 3 cases with chronic adhesive pericarditis	44
Cardiac valvular disease, including 2 having also congenital acyanotic lesions	118
Aortic insufficiency, including 1 with chronic adhesive pericarditis	8
Double aortic lesion	1
Aortic insufficiency and double mitral	1
Double aortic and double mitral	1
Mitral insufficiency	42
Mitral stenosis	21
Double mitral	44
Aortitis	1
Total	191

Physiological Diagnosis Disregarding sinus arrhythmia, which is found both in normal children and in children with heart disease, four pupils showed pathologic conduction systems, as follows: two had heart blocks, one had left and right premature ventricular beats with some intraventricular conduction delay, and one had premature contractions of which the point of origin remained unknown, as there was no opportunity for electrocardiographic study.

The *Functional Classification* varied in a number of children during the period of observation, but on the average, the cardiac capacity for exertion was as follows:

	No. of Cases	Per Cent
Class 1	131	68.6
Class 2a	41	21.5
Class 2b	15	7.9
Class 3	4	2.1

TABLE II

Heart Conditions in School Children Surveyed

Total number of pupils' medical records reviewed 33,293

	Number of children	Per cent
Pupils with suspected cardiac abnormality nominated by school physicians for study	863	2.6
Pupils for whom medical histories were obtained	391	1.14
Abnormal symptoms or signs relative to the heart were found in	350	1.05
Organic heart disease	191	0.6
Congenital heart disease (including two having also acquired lesions)	30	0.09
Acquired heart disease	161	0.5
Class E	113	0.33
Class F	46	0.13
No heart abnormality	41	

When the school population was divided into the younger and older children, or elementary and high school pupils, the respective enrollments and incidence of heart abnormalities found were as follows:

TABLE III
Heart Abnormalities in Younger and Older Children

	Elementary school (ages 6-14 years)		High school (ages 15-18 years)		Total	
No of pupils on roll	24,193		9,154		33,293	
	No	Per cent	No	Per cent	No	Per cent
Organic heart disease	111	0 5	80	0 9	191	0 6
Class E	74	0 3	39	0 4	113	0 33
Class F	30	0 12	16	0 2	46	0 13
Total abnormal hearts	215	0 9	135	1 5	350	1 1

RESTRICTION OF PHYSICAL ACTIVITIES

To insure the teacher's cooperation in restriction of the pupil's physical activities in school, the physician treating the child certifies on a blank form as to the duration and the cause of the excuse from exercises. The school physician may act for the family doctor. In either case, the certificate may be honored for 1, 2, or 3 months, and has to be renewed thereafter, unless it is endorsed by the medical supervisor. The supervisor has the authority to approve the certificate for a longer period of time, or even for the duration of the pupil's entire school life. In addition to the cause and duration of the restriction of physical activities, the exercises allowed are indicated and checked on the certificate as follows:

- 1 Competitive sports, requiring considerable exertion
- 2 Vigorous exercises on gymnasium apparatus. Running and jumping
- 3 Calisthenics and general exercises, simple games and play. These activities require little running or muscular effort
- 4 Very mild exercises (movements of arms, legs, neck and trunk)—duration 10 minutes
- 5 Very mild exercises (movements of arms, legs, neck and trunk)—duration five minutes

These listed physical activities are not descriptive of the degree of exertion required. I have therefore secured from the director of physical and health education, Mr. Grover W. Mueller, an interpretation of the classifications which appear on the certificate. The numbered physical activities are briefly described by Mr. Mueller, as follows:

INTERPRETATION OF CLASSIFICATIONS OF RESTRICTION OF PHYSICAL ACTIVITIES

- 1 Football, basketball, soccer, track and field events, lacrosse, field hockey, ice hockey, wrestling, boxing, competitive swimming, etc. These activities are characterized by vigorous activity, many moments of minimum effort, and many instances of sustained effort. The competitive element stimulates continuation of effort and participation which in the absence of such stimulus would be interrupted by intervals

of rest or relative inactivity. Speed, endurance, effort, and skill are the main physical qualities involved. Stimulation of the emotions and of the circulatory and respiratory systems is pronounced.

2 Vigorous exercises on the parallel and horizontal bars, rings, horse, buck and mats, hopping and jumping, vigorous dancing, such as folk dancing, non-competitive running, except that the running often is a part of competitive games of low organization, thus often resulting in vigorous running. The activities on the apparatus are characterized by the physical qualities of strength and skill, the running, hopping, and jumping are characterized by stimulation of the circulatory and respiratory systems. Great momentary effort frequently occurs, but effort is not sustained for more than a few moments and stimulation is not nearly so great as in Group 1. Emotional stimulation is slight.

3 General free exercises (calisthenics), mild forms of dancing, mild exercises on apparatus which are done in hanging and sitting positions, simple games and play. These activities involve mild contraction and extension of most of the muscle groups. The activity is alternated with regular short intervals of rest, effort is neither great nor sustained, there is only slight physiological stimulation, strength is involved only momentarily and in slight degree, skill is involved, consisting mainly of hand, arm, and eye coordination. Running is either in one spot or over short distances at moderate speed. The competitive element is lacking entirely, and no emotional stimulus is involved.

4 General free exercises (calisthenics) and simple play forms. These free exercises involve very mild contraction and extension of most of the muscle groups. They differ from those in Group 3 in that the exercises are more localized, they are not repeated so often, the intervals of rest are more frequent and of longer duration, and many of the exercises are done in the sitting and lying positions. Pupils may stop at any time they feel tired. Some exercises are done against mild resistance set up by a second person. The play forms involve little effort and consist almost entirely of hand, arm, and eye coordination, such as throwing rubber quoits, and throwing a ball over a short distance at a goal. In none of these exercises is strength involved except in the mildest possible degree. Running, hopping and jumping as well as any other activity which stimulates the circulatory and respiratory systems in any but the mildest degree are omitted entirely.

5 The activities in this group are identical with those in Group 4. The difference in the two groups is entirely in the total amount of physical work done. In Group 5 half as much work is done in one-half as much time (5 minutes) as in Group 4 (10 minutes).

Depending on the degree of the pupil's handicap there are four more listed "physical activities" each requiring less and less energy in successive degrees.

6 Walking only—10 minutes

7 No exercise, but ordinary activity throughout the school day

8 No exercise. Full day attendance. Rest during recess period. Pupil is allowed to move from room to room and to use stairs without regard to movement of classmates. Use of school elevator if there is one.

9 No exercise. Same privileges as number 8. Pupil is allowed to stay home in the afternoon to rest, whenever necessary.

The above classification of restrictions of physical activities has a definite relation to a pupil's physical capacity for exertion. It may be well therefore, to recollect at this time the standard classification of Functional Capacity

approved by the American Heart Association, and later discuss the application in school of the classification of restricted physical activities to the given functional capacity of the pupil with heart disease. The two together will permit a better correlation between the pupil's routine in the school and the cardiac capacity for exertion.

FUNCTIONAL CLASSIFICATION OF PATIENTS WITH ORGANIC HEART DISEASE

Class 1 Patients with organic heart disease, able to carry on ordinary physical activity without discomfort

Class 2 Patients with organic heart disease, unable to carry on ordinary physical activity without discomfort

a Activity slightly limited

b Activity greatly limited

Class 3 Patients with organic heart disease and with symptoms or signs of heart failure when at rest, unable to carry on any physical activity without discomfort

CORRELATION OF FUNCTIONAL CAPACITY WITH RESTRICTIONS OF PHYSICAL ACTIVITIES

I am frequently faced with the problem of correlating the functional capacity of the child with heart disease with the restriction of physical activities in the school. At times I am asked to endorse the family physician's request for the same. Children have to be guarded against participating in physical exercises to a prohibitive degree and against failing to indulge in permissible activities. The former may aggravate the cardiac condition or, through fatigue, lead to serious accidents, while the latter deprives the pupil of a necessary amount of physical culture and scholastic development. As a rule, though, it is safe to assume that the average child with heart disease will do all he can. Only in rare instances, as in the child who is not proficient in the activity, will he attempt to dodge the gymnastic requirement of the curriculum. Although a child with a Functional Capacity of Class 1, for instance, can usually be as active as any child that has no heart disease, it is not advisable to permit him to indulge in competitive sports which may over-stimulate activity beyond his endurance. Rather, it seems to me, the pupil should indulge in physical activities to a moderate degree that will satisfy his desire for athletics, and yet avoid risking a possible temporary heart failure or permanent aggravation of the heart condition. The avoidance of overexertion is very important, and the ability of a patient with organic heart disease "to carry on ordinary physical activity without discomfort" does not seem to me to be so universally applicable to school children as to adults. High school pupils, especially, routinely indulge in vigorous physical training and competitive sports which may call for extraordinary physical activities that are not safe for one with heart disease, even if the functional classification is class 1.

Furthermore, the older children, in the high schools, can be taught the danger signals, and warned to cease activity upon becoming aware of palpi-

tation or dyspnea. The younger children, however, in the elementary schools, may frequently fail to remember these sensations of heart beating and shortness of breath. Taxing the heart that has a chronic structural defect, such as valvular lesion, with a great amount of non-competitive activities may be often harmless. When heart disease is in the active stage, however, the problem is a more difficult one, and much greater precaution has to be exercised against further damaging the myocardium or causing a reactivation of a quiescent lesion. In other words, a strain on the mechanical defect of the circulation is of little danger. Inflammation, or activity of infection, however, requires not only restricted activities, but rest and prolonged convalescence for arrest or recovery of the process. Some systemic conditions as underweight, overweight, or the presence of other relevant physical defects in cardiacs may also require a suitable modification of the general principles of restriction of physical activities. When a complete cardiac diagnosis (etiological, anatomical, physiological and functional) is considered together with the full meaning of the numbered physical activities, the correlation of the functional capacity of the cardiac with the restriction of physical activities in the school becomes facilitated. Still, it is difficult to be dogmatic, as cardiacs with different anatomical diagnoses, although having the same functional classification, may require different restrictions of physical activities. I realize also, that my correlations may appear to some physical health educators to be too conservative, and to some physicians to be too radical. Experience has shown, however, that to err on the safer side is a mistake on "the side of the angels." I have therefore been recommending the following correlations:

TABLE IV
Correlation of Functional Capacity with Restriction of Physical Activities

Functional capacity	Physical activity Number allowed (highest)
(No school child with organic heart disease)	No 1
Class 1 (mild cases of congenital acyanotic or acquired lesions)	No 2
Class 1 (depending on the anatomical and physiological diagnoses)	No 3, 4 or 5
Class 2a	No 6 or 7
Class 2b	No 8 or 9
Class 3	No 9

WHEN IS RHEUMATIC INFECTION INACTIVE?

The question of whether rheumatic heart disease is in the inactive stage is particularly important to decide before the child is allowed to attend school, or return to it after any acute illness. As previously mentioned, the problem is also vital for the determination as to how much the child should be allowed to do in the school. It may be well, therefore, to review the his-

tory, physical signs and other findings that assist in ruling out activity of rheumatic infection

During the inactive stage of rheumatic infection

- 1 The child is free from any symptoms relevant to the infection
 - 2 He presents a good general appearance and absence of pallor or cyanosis
 - 3 He has good body weight
 - 4 He has a rectal temperature of 100° F or less
 - 5 His pulse rate is not over 100 a minute, and after exercise the rate returns to pre-exercise rate within three or four minutes
 - 6 He is free from fatigue when not exercising
 - 7 His systolic blood pressure and pulse pressure are within normal limits
 - 8 There is cessation of increasing cardiac enlargement
 - 9 There is freedom from evanescent adventitious pericardial, myocardial or endocardial sounds, pathologic conduction, or signs of heart failure
 - 10 There is freedom from a focus of active infection, as in the upper respiratory passages
 - 11 There is freedom from rheumatic nodules, skin eruptions, or hemorrhages
- Further investigations confirming the inactivity of the infection are
- 12 A normal hemoglobin, and red and white cell counts
 - 13 A sedimentation rate within normal limits
 - 14 A normal respiratory vital capacity
 - 15 An electrocardiogram that is free from deviations suggestive of rheumatic heart disease (Although not pathognomonic, prolongation of the P-R interval, alterations of the rhythm normal to children, and certain S-T or R-T and T-wave changes are characteristic deviations from electrocardiograms that might otherwise be considered within normal limits)
 - 16 An unchanging cardiac contour on roentgenologic and esophagaphic tests

DOES HEART DISEASE BECOME WORSE DURING SCHOOL YEARS?

Whether school life aggravates a child's heart condition depends much on several factors entering into the condition of the cardiac and his hygiene of life. It depends on an early complete cardiac diagnosis, a suitable restriction of physical activities, avoidance of school attendance during the active stage of the infection and, as previously mentioned, adequate convalescence after any other disease before school attendance is resumed. In my experience, heart disease frequently develops during—not necessarily because of—school activities, and in many cardiacs the condition becomes aggravated during the average twelve years of education. Space does not permit the citation of numerous examples. On the other hand, I have seen

many pupils who have gone through their greater part of school life with hardly any aggravation of the cardiopathy. It is true that a person with rheumatic heart defects can usually live comfortably the larger part of the span of expected life, but there are exceptions. Generally speaking, the prognosis of the child with heart disease depends on the early discovery of the condition, the degree of cardiac enlargement, the state of myocardium and the particular valves involved, the rhythm, the exercise tolerance, the education and preparation for a vocation with minimum additional damage to the heart, and the selection of a suitable vocation and harmless avocations.

CONCLUSIONS

1 The medical records of 33,293 children enrolled in Philadelphia public schools have been reviewed for abnormal heart findings. Of 863 pupils listed for observation of their hearts by 11 school physicians, 391 were considered worthy of studying. The study has been made with the aid of an adequate history of juvenile rheumatic infection, and physical examinations for the detection of circulatory diseases. Examination was made twice at an interval of about one year, and in many cases, a third examination was made in 1936. The thermometer, stethoscope, and blood pressure apparatus were used, but, with several exceptions, no other instrument of precision was employed.

2 For recording moderate cardiac hypertrophy, a new landmark on the anterior chest wall is being suggested. Its name is "preaxillary" line. The preaxillary line is an imaginary line on the front of either side of the chest, drawn vertically downward, midway between the midclavicular and anterior axillary lines, and parallel to them. It divides vertically the surface area of the chest wall between the midclavicular and anterior axillary lines exactly in half. Unlike the parasternal line which is similarly drawn from the medial half of the clavicle, the preaxillary line does not take origin from the outer half of the clavicle. The advantages of the use of the preaxillary line in chest examinations are described.

3 It is agreed that the parents, the family physician, the pediatrician, the cardiologist, and the hospital clinics form the main agencies protecting the children against the spread and aggravation of juvenile rheumatic heart disease. However, it is suggested that the school physician and nurse, and the school principal should also be enrolled in a permanent campaign to assist in the detection and amelioration of rheumatic heart disease in children. The school years are a very important period in the child's physical life and development, and have greater potentialities for the good or evil of a child with heart disease than of a healthy pupil. Perhaps the combined efforts of those named above can guide many of these unfortunate children more safely through the early educational years, prepare more wisely for a suitable vocation, and at the same time choose safe avocations. It is possible that such

wholehearted cooperation may reverse the tide, and cause a decrease in the incidence of rheumatic heart disease, not only in children, but in adults

Acknowledgments Directly and indirectly, a number of physicians, a greater number of nurses and clerical assistants, have kindly helped to assemble the data which made this report possible. Several school principals have cooperated even to the extent of arranging for physical examinations after the schools had officially closed. I regret the names are too numerous to mention here. I shall therefore be able to express my gratefulness only to Dr. Walter S. Cornell, Director, Medical Inspection of Public Schools, for his valuable advice, Drs. Samuel Baron and M. W. Benjamin, for their frequent help, and Miss Fay Ziegler and Miss Marie A. Gallagher for their diligent work in tabulating the data. Finally, may I be pardoned if I specifically mention here my great obligations to my wife in the preparation of this report.

GONOCOCCAL ENDOCARDITIS TREATED WITH ARTIFICIAL FEVER (KETTERING HYPERTHERM) *

By ROBERT H WILLIAMS, M D , *Nashville, Tennessee*

It has been known for many years that the gonococcus is quite susceptible to heat ^{1,2} It remained for Carpenter, Boak, Mucci and Warren ³ to determine by careful thermal death time gradient studies that 99 per cent of the cultures of several strains of gonococci are killed in vitro by 4 to 5 hours exposure to a temperature of 105.8° F With the Kettering hypertherm even higher temperatures over longer periods of time may be administered to patients with comparative safety The excellent clinical results obtained with this form of treatment in various gonococcal infections strongly suggest that the thermal death point of the organisms in vivo approximates that found to exist in the in vitro experiments of Carpenter et al

Within the last 15 years numerous authors have reported case studies of gonococcal endocarditis ^{4,5,6} A uniform feature of the reports has been the expression of a gloomy attitude regarding the efficacy of any form of treatment, once the organism has become established on a heart valve The present communication is concerned with the results obtained by treating one case of verified and one of probable gonococcal endocarditis with artificial fever (Kettering hypertherm) † The former is reported in detail as there have been no reports of necropsy findings in patients with gonococcal endocarditis who died after fever treatment

CASE I

History L L, a colored man of 24, was admitted to the Vanderbilt University Hospital July 15, 1936, complaining of weakness and chills Five weeks previously he developed coryza, sore throat, non-productive cough, slight pain in the upper mid-portion of the chest, generalized aching, malaise and fever A few days later a chill occurred, followed by slight swelling of the ankles, left knee and right elbow These joints remained painless and the swelling lasted only a few days After 10 days confinement to his home he felt much better although he did not entirely recover On July 10 he noticed a sudden increase in weakness and malaise He became dyspneic on exertion and developed edema of the feet and legs The next day he had a chill lasting 30 minutes On July 15 he had a second chill and his temperature was 105° F

There was no history of gonorrhea or syphilis

Physical Examination He was a well developed and well nourished negro who appeared acutely ill He perspired freely and the respirations were fast and deep The sensorium was clear The mucous membranes and conjunctivae were pale and

* Received for publication February 4, 1937

From the Department of Medicine, Vanderbilt University School of Medicine, Nashville, Tennessee

† This apparatus was supplied to Vanderbilt University Hospital through the kindness of Mr C F Kettering, director of the Division of Research, General Motors Corporation, and Dr Walter M Simpson, Miami Valley Hospital, Dayton, Ohio

slightly icteric. The skin was hot (temperature 104.4°) and exhibited numerous small red lesions over the tibiae. These were 1 to 3 mm in diameter and did not blanch on pressure. The nasal mucosa was injected and swollen. The tonsils were moderately large and reddened. The lungs were normal on physical examination. No cardiac enlargement was noted, but there was a long, loud, harsh systolic murmur of maximum intensity at the apex and transmitted to the left axilla and over the entire precordium. The second pulmonic sound was accentuated. The pulse was rapid (100), regular and of good volume. The blood pressure was 118 mm of mercury systolic and 80 diastolic. The abdomen was distended and signs of a small amount of free fluid were present. The liver edge was firm and smooth and extended 4 cm below the right costal margin. It was not tender. The spleen could be felt 5 cm below the left costal margin. A circumscribed smooth scar was present on the prepuce. The prostate was normal in size but slightly soft. The joints were normal. There was moderate pitting edema of the feet and legs.

Laboratory Data Urine, clear and yellow, specific gravity 1.008, acid reaction, no albumin and no sugar, the sediment contained occasional white blood cells but no red blood cells or casts. Red blood cell count 3,550,000, hemoglobin 8.5 gm, white blood cell count 15,100, neutrophils 61 per cent, eosinophils 1 per cent, lymphocytes 33 per cent, monocytes 5 per cent, no malarial parasites. The Wassermann reaction and the Kahn test were positive. Non-protein nitrogen 21.4 mg per cent, icterus index 9, total serum protein 7.07 gm per cent (albumin 2.62, globulin 4.45). Stools were of normal appearance and showed no pus, blood or parasites. Bromsulphalein liver function test 40 per cent retention in 30 minutes. The Takata-Ara test was positive. The galactose tolerance test showed a decrease in tolerance. The red blood cells exhibited normal resistance to hypotonic salt solutions. Roentgen-ray examination of the chest, pelvis and abdomen was essentially normal. Agglutination tests with *B. typhosus*, *B. paratyphosus* A, B, *B. melitensis* and *B. abortus* were all negative.

Course He ran a septic course with constant leukocytosis (averaging 12,000), intermittent fever with daily fluctuations of 6 to 10 degrees and occasional chills. Jaundice and ascites slowly but steadily increased. Frequent examinations of "thick drop" preparations for malarial parasites were negative. He was given a therapeutic test with quinine for five days, without notable change. During the three weeks preceding death (August 14) he received weekly injections of bismuth salicylate and was given 25 drops of a saturated solution of potassium iodide three times daily. Blood cultures obtained July 16, 17, and 20 showed no growth, while those obtained July 22 and 29 and August 6 contained gonococci. On August 6, the urine showed a small amount of albumin, bile, a few erythrocytes and leukocytes and numerous granular and cellular casts. Evidence of renal damage rapidly increased. By August 8, the 24 hour urine excretion had fallen from 2,000 to 400 cc, in spite of a fluid intake of over 2,500 cc, and the urine contained a moderate amount of albumin, bile, and numerous red blood cells. On August 8, 3,500 cc of turbid reddish yellow fluid were withdrawn from the peritoneal cavity, its specific gravity was 1.004, the erythrocyte count 5,625, leukocyte count 1,875. No bacteria were demonstrated by smear, culture or guinea pig inoculation.

With full recognition of the extremely gloomy prognosis because of the presence of gonococcal endocarditis associated with severe liver and renal damage, he was placed in the Kettering hypertherm on August 10. His temperature was maintained at an average level of 105.5° F (rectal) for six hours. To our surprise he bore this treatment fairly well. He was afebrile for the next 20 hours and his temperature never returned to as high a level as had previously existed. However, he appeared more stuporous. His 24 hour excretion of urine was 700 cc. On August 11 a blood culture was made from which no gonococci were grown. On August 12 he became anuric. On August 13 he received his second fever treatment. On this occasion his

temperature was held between 106 and 107°, averaging 106.7°, for five hours. This treatment, as the first, was apparently well tolerated. However, the stupor increased and he remained anuric (non-protein nitrogen 133 mg per cent, carbon dioxide combining power 29.1 volumes per cent). He died on August 14.

Clinical Impression Acute bacterial endocarditis (mitral valve), due to gonococcus, syphilitic cirrhosis of liver, ascites, jaundice, embolic glomerular nephritis, uremia, anemia secondary to infection.

Necropsy Report Autopsy performed two hours post mortem. The sclerae, subcutaneous fat and, in varying degrees, the viscera were jaundiced. Peritoneal cavity contained about 1,000 cc of greenish-red fluid. Pericardial cavity. The surfaces were smooth and glistening, about 40 cc of clear fluid were present. Heart Weight 270 grams, epicardium, myocardium and all valves, except the mitral, appeared normal. On one mitral leaflet was a firm non-friable vegetation 6 to 9 millimeters above the surface. On the opposite leaflet was a similar but smaller vegetation. These vegetations were so firmly adherent that it was felt certain that they contained a great deal of fibrous tissue (figure 1). There was slight ulceration of the margin of one cusp. The chordae tendineae appeared normal. Lungs. A small amount of atelectasis was present in the lower lobes. Gastrointestinal tract. Negative. Liver Weight 1,800 grams. The surface was nodular and in several places broad fibrous bands cut deep in the parenchyma (figure 2). A flattened, tongue-like projection extended over the spleen. Much resistance was encountered in slicing the liver. Cut sections revealed extensive scarring with broad fibrous bundles interlacing and surrounding islands of raised, reddish-yellow tissue. Scattered here and there, but denser in the left lobe than elsewhere, were varying sized and shaped grayish yellow, soft areas of necrosis with surrounding red zones. The gall-bladder and bile ducts appeared normal. Spleen Weight 940 grams, the pulp was firm, dark red, friable and densely studded with infarcts of varying ages, some of the older ones having become somewhat softened. Kidneys. The weight of the right kidney was 210 grams, and the weight of the left kidney was 200 grams. The capsules stripped easily, leaving smooth surfaces. The cut surfaces were pale and showed many small reddish splotches, thought to represent small hemorrhagic foci with some necrosis. Genito-urinary tract. The ureters, bladder, seminal vesicles, epididymes and prostate were normal. Brain. Negative.

Microscopic Examination Heart. Nothing remarkable was found except in the mitral leaflets. At the site of the vegetations were seen dense hyalinized fibrin deposits containing scattered polymorphonuclear leukocytes. There were two small foci of polymorphonuclear leukocytes beneath the surface of the valve. Beneath this process was a more chronic inflammatory reaction with an associated healing reaction as evidenced by the invasion with many fibroblasts and the formation of many small blood vessels (figure 3). Lungs. Atelectasis and slight passive congestion were present. Liver. The normal architecture of the liver was almost entirely destroyed. The sections showed a very large amount of fibrous tissue encircling varying sized islands of liver cells. In the fibrous tissue were many bile ducts, scattered lymphocytes, plasma cells and macrophages. In some areas there were polymorphonuclear leukocytes in and around the ducts. All the liver cells in some of the lobules were normal, whereas others had normal cells in the periphery, but the entire midzonal and central part showed uniform karyolysis of both nucleus and cytoplasm. At the edge of these areas of necrosis were rows of polymorphonuclear leukocytes. No thrombi were seen in vessels. No typical gummata were present. Spleen. There was marked engorgement of all sinuses and hemorrhages were scattered throughout the organ. Many polymorphonuclear leukocytes were present in the pulp. There were many areas of necrosis partly infiltrated with blood which had the appearance of infarcts. There was a proliferation of fibroblasts in some of these areas. Pancreas. One acinus

FIG 1 Healing gonococcal vegetations on mitral valve. Arrow 1 indicates a small ulcerated vegetation undergoing healing. Arrow 2 indicates the site of a lesion in which the healing process is more advanced.

FIG 2 Liver Note the typical cirrhotic changes on the surface of the organ and the huge scars with resulting deformity (hepar lobatum)

FIG 3 H and E stain Healing on mitral valve ($\times 500$) (See figure 1)

showed polymorphonuclear cells in its lumen whereas the remainder appeared normal, but there was edema and slight lymphocytic infiltration in the interstitial tissue. Adrenals: There was congestion of the vessels surrounded by foci of mononuclear cells but otherwise the organs were normal. Kidneys: There was swelling of the glomerular endothelium and a few of the endothelial cells were pyknotic. Many of the glomeruli showed intra-capillary hyalinization. The capillaries contained an increase in polymorphonuclear leukocytes. Some of the tubules contained polymorphonuclear leukocytes and albuminous material. The interstitial tissue was infiltrated with macrophages, plasma cells and lymphocytes. Seminal vesicles, epididymis, testis, bone marrow and brain: Essentially negative. *Bacteriology*: Smears and cultures from the vegetations yielded no organisms. Cultures of the heart's blood gave no growth. Smears from the prostate, liver and spleen contained no organisms. Stains of the mitral vegetations with hematoxylin-eosin, Gram's iodine and Giemsa stain failed to reveal organisms.

Anatomical Diagnosis: Acute endocarditis, mitral, gonococcal, syphilitic cirrhosis of the liver, infarcts in spleen, embolic, acute nephritis, embolic, pulmonary atelectasis, obstructive (with mucus), passive congestion of lungs, icterus, ascites.

This case report is of especial interest because of the following points: (1) an extremely ill person was treated in the Kettering hyperthermia without treatment complications, and (2) following treatment with hyperthermia gonococcemia disappeared ante mortem and the heart's blood and gonococcal vegetations were found sterile post mortem.

The clinical diagnosis was difficult because of the co-existing liver disease. By the time the data were correctly analyzed the patient had experienced a progressive septic illness for five weeks and exhibited evidence of severe liver disease and renal damage with uremia. His condition was such (uremia, hepatic insufficiency) that it was felt that he might not survive the first fever treatment. However, it was well tolerated. A blood culture taken the following day was sterile. The second treatment resulted in no reaction which could be related to hyperthermia in spite of the fact that the uremic state steadily progressed. At necropsy no organisms could be grown from the mitral vegetations or heart blood and none could be found on smear or with special tissue stains. There was but a small amount of fibrin and only a few polymorphonuclear leukocytes at the site of the vegetations and evidence of healing was well established.

The areas of necrosis in the liver were interpreted as resulting from emboli or from an exacerbation of syphilitic endarteritis brought about by the combination of bismuth, iodides and heat. The possibility that fever treatment may have intensified the manifestation of uremic intoxication was considered. The necropsy findings threw no light upon this.

CASE II

History: On May 2, 1936 there was admitted a white male salesman, aged 46, who for three weeks had been having "cramps" in various muscles, had felt easily fatigued, and had noted loss of energy. Most of his symptoms, however, appeared very suddenly four days preceding admission when he developed a "hard chill," a fever of 104° F, generalized aching and profound malaise. The following morning

he noticed numerous small, sore, red spots scattered in the skin of various parts of his body, but localized chiefly on the extremities. The day preceding admission he developed pain and slight swelling in the knees, ankles and wrists.

He had gonorrhea at the age of 26.

He was told eight years before the present illness that he had a "slightly leaking heart valve."

Physical Examination On admission he appeared acutely ill. His skin was hot (temperature 103° F) and he was perspiring freely. Scattered on the distal portions of the extremities, and to a much less extent over the other parts of his body, were numerous circumscribed, purplish-red areas in the skin, varying in diameter from 2 mm to 1 cm. Some of these were slightly tender. Many showed a central white area of necrosis and a few showed vesiculation with accumulations of seropurulent fluid. No petechiae were present in the mucous membranes. The blood pressure was 145 mm of mercury systolic and 90 diastolic. The apex beat was in the fifth inter-space, 9 cm from the midsternal line. There were no shocks or thrills over the precordium. There was a moderately loud, blowing, systolic murmur, best heard at the mitral area, transmitted to the left axilla. There was slight swelling and pain about the ankles and wrists. Only slight pain was excited by manipulation of the joints and it was felt that the inflammation was in the periarticular tissues rather than in the joints proper.

Course His course was that of septic illness with "spiking" temperature chart and occasional chills. The leukocytes ranged from 8,000 to 12,000 per cm. The petechiae gradually faded over a period of four weeks. The swelling about all the joints, except the right ankle, subsided in a few days. During the second week the right ankle became tremendously swollen, exquisitely tender and red. Pus was aspirated from this joint and gonococci were demonstrated by smear and culture. During the second week in the hospital the systolic murmur at the mitral area changed in quality and intensity. It became louder and harsher. No gonococci could be demonstrated from urethral or prostatic excretion, but there were many pus cells. Blood cultures taken on May 2, 4, 8 and 15 yielded no growth. May 4, agglutination tests with *B. typhosus*, *B. paratyphoid A*, *B. paratyphoid B*, *B. melitensis*, *B. abortus* and *B. proteus X-19* were negative. These agglutinations were repeated May 14 and were again negative. An electrocardiogram, May 4, showed the S-T segment to form the ascending limb of a high peaked, diphasic T-wave in Lead II, S-T segment was of low origin in Lead III. On May 8 the complexes were normal except that T₁ and T₂ were slightly diphasic. On May 19, the complexes were interpreted as being due probably to transient myocardial disease (embolism?).

He was placed in a Kettering hypertherm on May 26. His temperature was maintained between 105 and 106° F for five hours. Following this treatment his temperature returned to normal and remained practically normal thereafter. There was a marked decrease in the inflammatory reaction about the ankle. It was noted that the mitral murmur was less harsh. On May 29 he was given a second treatment. His temperature was held at between 106 and 107° F for five hours. The ankle continued to show steady improvement. He was given a third treatment June 2, when, after it had been maintained at 106.5° for two hours, his temperature suddenly rose to 108.2°. The patient developed evidence of impending collapse and treatment was discontinued. June 10 he was discharged free of symptoms, except for slight discomfort in the right ankle.

Six months later the patient reported that he had returned to his work a few weeks after discharge from the hospital. His "follow-up" examination at this time was essentially normal except for the persistence of a faint systolic murmur at the mitral area.

The sudden onset of this patient's illness with a chill and high fever, the presence of numerous large petechiae with areas of central necrosis, the high, septic temperature with occasional chills, the transient multiple arthritis with subsequent development of acute purulent monarticular arthritis from which gonococci were obtained, the presence of transient electrocardiographic alterations indicating acute changes in the myocardium, and the change in character of the apical murmur constitute convincing evidence of severe (metastatic) gonococcal infection and strongly suggest that gonococcal endocarditis was present. Recovery was prompt and complete, following treatment with artificial fever.

SUMMARY

1 A case history of proved and one of probable gonococcal endocarditis treated in the Ketting hypertherm are recorded.

2 In the proved case, fever treatment resulted in sterilization of the blood and, as established at necropsy, sterilization and healing of the endocardial vegetations. Death was due to co-existing syphilitic cirrhosis of the liver and uremia. At autopsy no pathologic changes were noted in the viscera which could be attributed to the effect of fever treatment per se.

3 In the case designated as probable gonococcal endocarditis with co-existing acute gonococcal arthritis, fever treatment resulted in prompt recovery.

SEVERE BONE-MARROW DEPRESSION FOLLOWING ARSPHENAMINE, REPORT OF TWO CASES WITH RECOVERY

By ABRAHAM LIEBERSON and ARTHUR WEISS, *New York, N Y*

THE authors delayed reporting the following two cases of arspenamine bone-marrow depression for several years in order to make certain of the permanency of the recovery which occurred in both cases. The blood dyscrasias occasionally caused by arspenamine have been reported in the literature mainly under the headings of their outstanding clinical manifestations, such as granulocytopenia, agranulocytosis, thrombocytopenia, or aplastic anemia. A study of these reports and of the two patients who were followed carefully on the wards of Beth Israel Hospital has confirmed our belief that most cases may best be considered as early or late instances of the same toxic process which in its severest form causes complete aplasia of the bone-marrow.

CASE REPORTS

Case 1 L W, male, aged 50, cloak manufacturer, admitted May 4, 1933 because of weakness, fever, joint pains and frontal headaches of two weeks' duration, and a rash over his lower extremities which had appeared the preceding day.

The patient had a chancre confirmed by dark-field examination in 1918. Anti-luetic therapy was begun immediately and continued for two full years. The Wassermann examination was positive only once. After this there were no complaints referable to the disease except for a feeling of numbness and cold in the toes and finger tips for three years before his present illness. Two months before admission (March 1933) following exposure to infection the patient again developed a chancre, also confirmed by dark-field examination, thus providing an excellent example of that rarity—a second chancre. Intravenous therapy was begun and nine injections of salvarsan were given, twice weekly. The last six injections were followed in four to five hours by marked general reactions with chills and fever. The patient felt worse after each reaction, finally taking to bed two weeks before admission because of weakness, lassitude, aching joints, severe frontal headache, and moderate fever. The case was diagnosed as grippe, but the pyrexia and other symptoms failed to disappear. Three days before admission to the hospital, while crossing his left knee over his right, he experienced a sudden click in his left calf, this area became painful and hard, but not reddened. On the day of admission he developed a rash on both lower extremities which did not itch.

Physical Examination The patient appeared chronically ill, markedly pallid. No lymphadenopathy was present. The pupils were equal, regular and reacted well to light and accommodation. The tongue was not atrophic, the gums were normal, the teeth false. The heart was not enlarged, a soft systolic murmur was heard at the apex. The lungs were emphysematous. The liver was palpable two fingers below the costal margin as a smooth, non-tender mass, the spleen was barely palpable. Knee jerks, ankle jerks and other reflexes were normal. There was no loss of vibration or

position sense There were fine petechial hemorrhages (purpuric) over both legs, both arms and in the right axilla The tourniquet test (Rumple-Leeds phenomenon) was positive The left calf muscle was hard and tender

Laboratory Data

<i>Urine</i>	June 5	Sp gr 1.018, acid, amber, very faint trace of albumin, no glucose, no casts, no red blood cells, occasional white blood cells
	June 8	Arsenic is present
<i>Feces</i>	June 6	Blood and bile present
<i>Venous pressure</i>	June 5	7.5 cm
<i>Sedimentation rate</i>	June 5	130 mm in 45 minutes
	July 16	90 mm in 45 minutes
<i>Icteric index</i>	June 29	7
<i>Wassermann</i>	June 5	Negative
	June 18	Negative
<i>Blood culture</i>	June 29	Sterile
<i>Blood chemistry</i>	June 5	Glucose 133 mg per cent, non-protein nitrogen 26 mg per cent
	July 19	Fibrinogen 2.1 g/100 c.c. plasma
<i>Culture of pus from thigh</i>	July 18	<i>Staphylococcus aureus</i>
<i>Roentgen-ray of chest</i>	June 8	Shows normal heart, aorta and lungs
<i>Electrocardiogram</i>	June 9	Sinus tachycardia

The blood counts and the dates of transfusions are shown in the following table

Progress Notes The patient entered with a temperature of 101.2° F, but this rose to 106.2° the next evening, and varied between 102° and 105° for the next week. Intravenous sodium thiosulphate and repeated intramuscular injections of adenine and pentnucleotides in the first two weeks of his stay did not prevent the continued fall of the white blood count from 1900, with 48 per cent polynuclear cells, to 1,350 with 20 per cent polynuclears on the seventh day (June 10) and 1,600 with 32 per cent polynuclears on June 22, when the treatment was stopped.

A bone-marrow puncture over the upper third of the sternum was performed on the third day of his stay (June 6). The marrow was red, but appeared somewhat less cellular than normal. Microscopic examination revealed numerous normoblasts, no megaloblasts, no myeloblasts, many myelocytes, *metamyelocytes* and *stuffs*, the latter two predominating. There were few mature segmented neutrophils. No megakaryocytes were seen. The fact that pathologically the bone-marrow showed no increase in younger cells but an apparent decrease in mature elements ruled out definitely a truly organic aplastic anemia. The most probable diagnosis, considering the normal cellular elements found on biopsy and the neutropenia, thrombocytopenia and anemia shown by the peripheral blood was a toxic inhibition of the bone-marrow due to the arsphenamine. These bone-marrow findings were the rationale for transfusions, which were repeated about twice weekly in spite of failure of the patient's blood to respond to them.

June 17, 1933 The patient showed dryness and desquamation of the skin of the upper extremities, chest and back. The dermatologist considered the skin eruption an arsenical exfoliative dermatitis. There were many new petechiae over the chest, back and mouth at this time.

June 22 There was a small area of beginning ulceration between the hard and soft palate which lasted only a few days.

June 27 Purpuric manifestations were increasing while the white blood count showed a steady rise in polymorphonuclears. For the first time the patient showed

some clinical improvement. The temperature, which ranged between 101° and 106° F rectally the first three weeks, sought a lower level (100° to 103° F) now.

June 29. An erythematous area on the right hip was noticed, with a tendency to pustule formation, this cellulitis became softer and disappeared in about two weeks.

July 11. The hematoma of the left calf muscle, which always had been hard and non-tender, became softer and more tender.

From July 12 on, the blood and clinical picture showed steady improvement (table 1). There was only a sub-febrile temperature at this time, which later became normal. The patient felt a daily increase in strength. Upon his discharge ten and one-half weeks after admission he felt perfectly well except for the painful diffuse swelling of his left calf muscle due to an organized hematoma. His blood count on this day (August 16) was: Red blood cells 3,130,000, hemoglobin 60 per cent, white blood cells 3,600, polymorphonuclears 48 per cent. Discharge Diagnosis: Arspnenamine panmyelophthisis. Arsenical exfoliative dermatitis. Organized hematoma of left calf.

Follow-Up Notes. Patient had no complaints at any time when a follow-up blood count was done. The general condition was good, the heart, lungs, skin and joints negative. Blood counts were as follows:

Date	R B C	Hgb %	W B C	Polys	Monos	Staff	Eos	Lymphs	Monos
2/ 8/34	4,070,000	69	5,800	46%	54%	3%	3%	50%	4%
9/23/35	3,780,000	86	5,700	53%	47%	1%	4%	42%	5%
1/ 7/36	4,530,000	90	7,100	47%	53%	2%	5%	43%	10%

Comment on Case. The importance of the bone-marrow puncture in this case cannot be overemphasized, for it indicated that, although findings in the peripheral blood were those of an aplastic anemia (granulocytopenia, thrombocytopenia and erythrocytopenia) the bone-marrow was not aplastic. Its function was simply suspended. The biopsy bolstered up our faith in the efficacy of persistent transfusions during the first four weeks when the patient failed to show any clinical improvement, and when his condition appeared hopeless, because of the marked asthenia, hyperpyrexia and bleeding. We believe the repeated transfusions saved this man's life by tiding him over the acute emergency of toxic inhibition of the bone-marrow. It is interesting to note that when the patient's condition began to improve and his blood to show a rise in the polymorphonuclears, the infected areas on the right buttock and left calf became soft, fluctuant and purulent, and showed the more typical picture of an acute infection which is undergoing healing, whereas previously these areas were more indolent and showed no pus. This contrasts with the case of dysplastic granulocytopenia reported by Weiss and Goldbloom¹ where clinical improvement in an anal slough did not occur even though leukocytosis (up to 40,000 cells) followed several weeks of granulocytopenia. That patient died in spite of the return of the neutrophils because these cells, although plentiful in number, were of deficient quality, due to an irreparable injury to the mother-cell. In our present case, however, there was apparently no such injury to the mother-cell, for once

the bone-marrow resumed its hematopoietic function the patient's condition improved rapidly, and was no longer serious. The follow-up blood counts show that the recovery was complete, and there was no tendency to relapse.

Case 2 E. L., male, aged 32, manager, admitted June 19, 1933 with progressive weakness and bleeding from nose and gums for about one month.

The patient discovered he had a four-plus Wassermann in the course of a routine study for a "cyst" near the rectum about six months before. He immediately underwent a course of arsphenamine therapy, receiving an injection once a week for six weeks, until his Wassermann was negative. There were no immediate ill-effects except for mild nausea on the injection days. After this he received seven more injections at three-week intervals. The dosage was rather high (from 0.5 to 0.9 grams). He noticed that he was becoming progressively weaker and that he tired very easily. About three to four weeks before admission he began to bleed from the gums, and later had bleeding from the nose one night. The bleeding from the gums was intermittent, and became much worse five days before admission. Three days before his entry into the hospital his vision, which was failing, became so poor that he could not read the newspaper headlines.

Physical Examination The patient appeared extremely pale, subicteric, chronically ill. Pupils normal. Fundi rather pale with numerous hemorrhages, mostly along the course of vessels. The tongue was coated, the breath fetid, the gums bleeding. Slight enlargement of the cervical glands was present. The heart and lungs were negative. The liver was palpable at the costal margin, the spleen was not felt. The knee and ankle jerks were obtained on reinforcement. There was no loss of vibration or position sense in the lower extremities.

Laboratory Data

<i>Average Urine Analysis</i>	Sp. gr. 1.014, acid, amber, very faint trace of albumin, no glucose, no casts, rare red blood cells, rare white blood cells

	July 19 Fibrinogen 0.9 g./100 c.c. plasma
	June 20 Sinus tachycardia
<i>Electrocardiogram</i>	Aug. 4 Frequent ventricular extrasystoles

The blood counts and the dates of transfusions are shown in the following table

Progress Notes The patient at first was given sodium thiosulphate intravenously for two days and pentnucleotides intramuscularly for five days. This apparently had no effect on the white blood count, which fell to 1150 with 11 per cent polys on June 24 (table 2), when there was bleeding from the gums which lasted all day. In spite of repeated transfusions the patient's condition remained grave, gingival bleeding persisted, even though it would stop for a period shortly after a transfusion. Transfusions were given bi-weekly, but with little apparent effect on the blood picture. On July 25 the patient's temperature, which had remained about normal after the first week, rose to 104° F. A fissure-in-ano with large hemorrhoids and an ischio-rectal abscess were found to be the cause of the fever. The abscess was incised on July 31, after which time the temperature fell to normal. The wound failed to granulate, however, and by August 11 there was still no evidence of healing. The patient was failing fast. Bleeding from the gums and nose increased, diminishing only slightly for a short period after a transfusion. Surprisingly enough, however, about August 17 and 18 a sudden turn for the better occurred. The wound began to granulate. On August 21 the patient for the first time stated that he felt well. Though there was

1934													
1/20	4,010,000	80	6500	62	38	5	56	1	33	5		platelets normal	
3/14	4,450,000	86	7000	65	35	5	60	0	31	4		platelets normal	

no appreciable change in the white, red, or platelet count the patient was now able to sit up in a chair. On August 25 the red blood count, hemoglobin, and white blood count fell, and three more transfusions were given even though the patient was feeling better and the bleeding from the gums and nose had stopped. On September 16, 1933, thirteen weeks after admission, the patient was discharged with 1,930,000 red blood cells, 42 per cent hemoglobin, 3,990 white blood cells, and 47 per cent polymorphonuclears. Although his blood picture did not show complete recovery by any means, he was clinically much improved. At home his private physician placed him on high doses of iron and ventriculin. With this medication, rest and high caloric diet he rapidly regained his former strength. A blood count taken four months after his discharge was normal in every respect, as were blood counts taken six, eight and ten months later. The patient has remained healthy and normal to date, weighs fully 200 pounds and has no complaints at all.

the count falls within two or three days to 20 per cent (or even as low as 12 per cent) of normal. If she gave no injection after the first one, the fall in white blood cells would continue to a level well below the 50 per cent, but later there would be spontaneous and complete recovery. However, if the second injection was given, the count would eventually fall below 12 per cent and recovery failed to take place. The myeloblastic elements, particularly the polymorphonuclears, were found depressed by the benzol. There was no destruction of the white blood cells in the circulating blood, but an inhibition of their formation. Only later with increasing doses was a depressive effect on the other tissues in the bone-marrow demonstrated (red blood cells and platelets).

Translated to human subjects, the primary action of benzol (arsphenamine) is depression of granulocyte formation, this action is early, and can be reversed if no more benzol is administered. However, with continued benzol doses, the later "secondary" actions are permitted to develop and an irreversible situation is brought about. The secondary effects are on the megalokaryocytes, causing not only a reduction in number, but also in quality of the platelets. The hemorrhagic diathesis that results leads to bleeding from the gums, nose, gastrointestinal tract, etc. The red blood cells are thus involved secondarily, suffering in proportion to this bleeding. Since benzol does not affect the red blood cells primarily there are no signs of regeneration—no reticulocytes, or nucleated red blood cells¹⁶. The final, late stage of arsphenamine bone-marrow depression is thus a "panmyelophthisis". If the bone-marrow has simply been depressed, there is some chance of recovery with repeated transfusions that tide the patient over the period of bone-marrow inactivity. Where a true aplasia of the bone-marrow has resulted, however, there appears to be little basis for any such hope. It is not possible to make this differentiation (depression or true aplasia of bone-marrow) from the study of circulating blood alone. It is of the utmost importance prognostically to perform a bone-marrow puncture in these cases. In case 1 a puncture was performed in the first week at the hospital and showed red bone-marrow with about the usual number of young cells, but few mature segmented neutrophils. This depression without aplasia of the myeloid system indicated that there was some bone-marrow tissue left to stimulate with repeated transfusions. The term "panmyelophthisis" we believe describes the condition of functional depression of the bone-marrow better than "aplastic anemia," a term which indicates organic depletion of the bone-marrow. This condition surely did not exist in case 1, and in all probability was not present in case 2, either.

A few words must be said about the clinical course shown by the two cases reported. "Panmyelophthisis" is a relatively late reaction of the body to arsphenamine poisoning and occurs typically several months after the beginning of arsphenamine administration. The "incubation" period is long here when compared with the toxic effects of arsphenamine on the liver

(where symptoms are likely to appear much earlier,—i e, during the first few weeks) This may be because the first symptoms of toxic action of arsphenamine on the bone-marrow are slight, there being only signs of general intolerance of the drug, such as the weakness, nausea and feverishness that case 1 experienced after each injection Moore and Keidel⁷ speak of itching or a fine rash as prodromata The only unmistakable sign of trouble, however, is the neutropenia It cannot therefore be urged too strongly that patients who show any intolerance of, or reaction to, arsphenamine injection should have a blood count performed By this means we can detect the neutropenic cases and stop administering the drug before irreversible damage has occurred Our therapeutic desideratum is to recognize intolerance of the bone-marrow to arsphenamine before a hemorrhagic diathesis or an aplastic anemia has set in By constant vigilance for the advent of neutropenia, we can recognize these cases early enough to stop the progress of the disease to the fully developed "panmyelophthisis," which, in spite of the best of treatment, is fatal in about 80 per cent of the cases¹³

At the stage when the disease is confined to the leukoblastic tissues (the first or "neutropenic" stage) the nucleotide administration as sponsored by Jackson¹⁶ may reasonably be given a trial In the later stages of panmyelophthisis, as in our two cases, nucleotide injection appeared to have no appreciable effect on the white blood cells The treatment is preferably the use of persistent transfusions until death or recovery supervenes

SUMMARY AND CONCLUSIONS

Two cases of complete bone-marrow depression several months after arsphenamine administration are reported An individual constitutional susceptibility of the bone-marrow to the toxic agent may explain the occurrence of this relatively rare disease In mode of onset, blood pictures and clinical characteristics such cases resemble very closely those due to chronic benzol poisoning Although there is no definite proof, it is likely that the benzol ring into which the arsenic is substituted in arsphenamine is responsible for the blood dyscrasias here described, and not the arsenic The relatively benign hemorrhagic diathesis occurring shortly after an injection of arsphenamine due to an "anaphylactoid" reaction of the thrombocytes is differentiated from the true depression of the bone-marrow caused by the slow accumulation of the toxin (benzol) and resulting in bone-marrow depression weeks and months after the administration began A study of bone-marrow depression in chronic benzol poisoning, and after arsphenamine administration indicates that the toxin most often shows an early affinity for the leukoblastic tissue in the bone-marrow Thus, the early and easily reversible action of arsphenamine on the hematopoietic system is most often a reduction in the white blood cells, particularly the polymorphonuclears Clinically this is expressed as a neutropenia associated with signs of lowered resistance—weakness, persistent colds, numerous smaller infections

tions, etc. If this early neutropenic stage is recognized and the arsphenamine administration stopped, the patient may be spared the later and frequently irreversible effects on the bone-marrow of the accumulating arsphenamine (benzol).

Reduction in the number and quality of the platelets, with consequent bleeding from the mucous membranes of the nose, mouth, gastrointestinal tract, etc. is more likely to be a later than an early effect. The bleeding alone explains the marked secondary anemia that finally occurs in most cases, although a direct depression of the erythroblastic tissues may be the cause of the erythrocytopenia in some. Thus the final, often irreversible, stage of the toxic action of arsphenamine (benzol) is a depression to a varying degree of all the elements of the bone-marrow. If puncture reveals a bone-marrow which is not aplastic, blood transfusions persisted in for many weeks may tide the patient over the period of temporary marrow inactivity, and lead to permanent recovery, as in the two cases reported. If a true aplasia of the bone-marrow has already resulted, however, the outlook is practically hopeless. The prognostic importance of bone-marrow puncture in this connection cannot be overemphasized. In any case, persistently repeated transfusions, no matter how ill the patient appears clinically, offer the only hope at this late stage of the disease, and are, therefore, always indicated in its treatment.

The authors are deeply indebted to Dr. I. W. Held for his encouragement and advice and to Drs. A. Grossman and M. Kramer for assistance in the difficult therapeutic problems presented by the cases.

BACILLUS FRIEDLANDER INFECTIONS¹

By GEORGE BAHR, M D , F A C P , GREGORY SHWARTZMAN, M D , and
EDWARD B GREENSPAN, M D , *New York, N Y*

IN the minds of most physicians and in almost all textbooks on bacteriology and clinical medicine, *B friedlander*¹ is associated with pneumonia and other infections of the respiratory tract. This traditional viewpoint is responsible for the fact that its common synonyms are *Bacillus pneumoniae* and *Pneumobacillus* and that its modern scientific designation according to the Bergey² bacteriological nomenclature is *Klebsiella pneumoniae*. Infections of other parts of the body with this organism are generally regarded as relatively less common.

Our bacteriological experience with 198 *B friedlander* infections is recorded because it contradicts this conception of the predominant rôle played by the organism in infections of various parts of the body. The observations to be reported in this paper, and a critical review of medical literature of the past 75 years, demonstrate that the respiratory tract and especially the lung is actually one of the less common sites of primary infection and that the current terminology serves to perpetuate a wrong emphasis concerning the usual portal of entry and the essential rôle of the organism in infections.

Friedlander discovered his encapsulated gram-negative bacillus in 1882 in spreads made post mortem from the lungs of eight patients who had died of pneumonia. For some four years thereafter it was generally regarded as the cause of pneumonia, until Weichselbaum's³ report upon the *Diplococcus pneumoniae* in 1886. Although Weichselbaum's observations upon 129 cases established the pneumococcus as the cause of lobar pneumonia, and minimized the relative importance of *B friedlander*, he observed the bacillus in microscopic spread in nine cases, isolated it in mixed cultures in six and in pure culture in three instances. He and Netter⁴ are widely quoted as accepting it as a less frequent cause of lobar pneumonia and bronchopneumonia because they found it in 7 or 8 per cent of their cases. It seems to have escaped notice that their observations as well as the reports of subsequent observers who confirmed their statistics were based upon postmortem bacteriology and, judged by more modern standards, are therefore of doubtful value. Bacteriological experiences reported on large numbers of cases during and subsequent to the World War indicate that *B friedlander* is encountered relatively rarely in pneumonia.

* Received for publication May 10, 1937.
From the Mount Sinai Hospital, New York.

Many authentic Friedlander bacillus infections of the lungs and other parts of the respiratory tract have been recorded in the literature, but in most instances it is obvious that the observer is reporting what is undoubtedly a rarity in his experience. Unfortunately, some of the recorded cases are unconvincing because they are based solely upon postmortem culture of the organism from a pneumonic lung or other tissue. Some represent influenzal pneumonia with a secondary invasion with *B. friedlander*. Others are chronic lung abscesses with mixed infections, or tuberculous cavitations with secondary *B. friedlander* infections. Still other cases are metastatic lung abscesses from a primary focus of infection within the abdomen. A case of lobar pneumonia recently reported by Bensley⁵ seems to us to have been due to pneumococcus type II and the *B. friedlander* invaded the blood stream only preagonally. Two of the largest and best described groups of *B. friedlander* pneumonia were reported recently by Solomon⁶ from Bellevue Hospital and by Bullowa⁷ from the Harlem Hospital, New York.

It is beyond the scope of this paper to review the voluminous literature upon this organism, except to state that it has been found in almost every part of the body. Yet almost every textbook of bacteriology and clinical medicine continues to lay stress upon its relationship to pneumonia and most of them state specifically that it may cause a severe, often fatal, but rather rare form of the disease. They usually mention some of the other sites of infection (Zinnser,⁸ Jordan,⁹ Park, Williams and Krumwiede,¹⁰ Topley and Wilson,¹¹ British Medical Research Council,¹² Ford,¹³ Stitt,¹⁴ Zinnser and Bayne-Jones¹⁵).

In this paper we have preferred to call the organism *B. friedlander* in preference to the synonyms which associate it with pneumonia and to such descriptive designations as *Bacillus mucosus capsulatus* and, for a subgroup, *Bacillus acidilactici*. Formerly we did not attempt to differentiate between the various types of Friedlander organisms because of the lack of clear cut bacteriological criteria. More recently Julianelle¹⁶ has divided the *B. friedlander* into three groups, A, B, and C, according to their serologic reactions. Some of the strains were identified serologically by cross agglutination with pneumococcus type II serum (Avery, Heidelberger, and Goebel¹⁷). The classification by Julianelle is being followed closely in our laboratory, but sufficient information is not yet available regarding the pathogenicity of the various types. For this reason, gram-negative bacilli showing well defined capsules and typical "gum drop" and stringy colonies on solid media were considered to belong to the *B. friedlander* group, provided these characteristics persisted for at least 3 to 4 passages through artificial media. It should therefore be understood that the term *B. friedlander* employed in this report implies the Friedlander group of encapsulated gram-negative bacilli.

RESPIRATORY TRACT

The presence of *B. friedlander* in stained spreads made from the sputum or the lung of a patient with pneumonia probably rarely escapes detection. Because of the traditional association of this gram-negative bacillus with pneumonia, its observation anywhere in the respiratory tract usually results in its prompt identification by means of the capsule stain.

On the other hand, so strong is the influence of medical tradition that gram-negative bacilli encountered in the intestinal tract or in the biliary or urinary passages are apt to be associated with the colon-typhoid group of bacteria and to be inoculated for identification upon the various sugar media. Unfortunately, many strains of *B. friedlander* and of *B. coli* form acid and gas in identical sugar media. Unless a capsule stain is made or attention is attracted by the mucoid character of the surface growth on solid media, observations upon sugar media may result in confusing the organism with the colon group. We can conceive of no better explanation for the conspicuous attention which *B. friedlander* continues to receive in bacteriological observation upon respiratory tract infections and the relative neglect of the more important rôle played by this organism in infections of the abdominal cavity.

In reporting cases of primary *B. friedlander* pneumonia, it is important to exclude the following:

- 1 Secondary invasions (often piecagonal) in cases of primary pneumococcus pneumonia
- 2 Influenzal pneumonia with secondary invasion of the affected lung by *B. friedlander* and a variety of other organisms
- 3 Chronic bronchiectases, lung abscesses and tuberculous cavitations in which a secondary *B. friedlander* infection has occurred
- 4 Metastatic infections of the lung from a primary focus of *B. friedlander* infection within the abdomen

In the authentic cases of *B. friedlander* pneumonia, the cut surface of the consolidated lung may appear peculiarly mucoid. Microscopically, the exudate in the alveoli presents a more mucinous appearance than the usual pneumonic lung and may contain large numbers of encapsulated gram-negative bacilli. The organisms may also be present in large numbers in the interalveolar capillaries.

TABLE I
Bacillus Friedlander Infections
198 Cases

Site	Number of Cases	Mortality	Bacteremia	
			No	Died
Gastrointestinal tract	61		1	1
Genito-urinary tract	50	8 (16%)	6	3
Biliary passages and liver	46	14 (30%)	6	5
Lungs and upper respiratory tract	25		1	1
Miscellaneous: skin, meninges, etc.	10		1	1
Vagina, uterus and adnexa	6		1	1

In our series of 198 infections, we have had only two cases of pneumonia in which the clinical and bacteriological evidence during life left no doubt that *B. friedlander* was the primary cause of the pulmonary infection. The rarity of primary Friedlander pneumonias is indicated by the fact that these are the only two proved cases observed at the Mount Sinai Hospital, New York, during a period of 36 years. In seven other cases of lobar or bronchopneumonia, *B. friedlander* was recovered from the sputum or lung during life in association with pneumococci or streptococci.

The organism was also recovered occasionally from pneumonic lungs at necropsy in association with other bacteria, usually pneumococci or streptococci. It may therefore have been a secondary invader or a postmortem contamination. Our experience leads us to believe that *B. friedlander* may at times gain entrance into the body preagonally from the intestinal tract. Postmortem spreads and cultures from pneumonic lungs are therefore of little value.

Other Infections of the Respiratory Tract Aside from the nine cases of pneumonia, of which only two are primary infections, the organism was isolated 16 times from other infections of the respiratory tract during life. The cases were as follows:

Pharyngitis	1
Acute otitis media and mastoiditis	3
Chronic otitis media	1
Suppurative sinusitis	3 (one with meningitis)
Thornwald abscess of the nasopharynx	1
Infected thyroglossal cyst	1
Submental abscess	1
Pleural effusion of cardiac origin	1 (contamination)
Pleurisy with effusion	1 (probably a contamination)
Chronic lung abscess	1
Empyema thoracis	2 (one probably a contamination)

One of the cases of mastoiditis developed a *B. friedlander* meningitis and a bacteremia.

The nine cases in which the organism was isolated from an infection in the nasopharynx, the sinuses or the ears contrast numerically with the 163 *B. friedlander* infections of the abdomen, of which 61 were due to perforative lesions of the intestines.

The organism is occasionally encountered in the normal flora of the upper respiratory tract and is undoubtedly responsible at times for infections in the sinuses and the ears. Because of the much greater frequency of its occurrence in the intestinal tract, our experience inclines us to regard its occasional presence in the upper respiratory tract with suspicion as a possible contamination, or as a secondary invader. Even when found repeatedly in pure culture from infected sinuses or ears, it may have been introduced by previous instrumentation.

Dr. Lee Hurd¹⁸ has recently called attention to the fact that 25 years ago *B. friedlander* infections of the upper respiratory tract, the sinuses and the ears were not such rarities as they are today. Comparative statistics of

25 years ago and of today reveal a striking diminution in the frequency of this type of infection. The use by many of the pioneer specialists of unsterile instruments with unsterile hands may possibly have been the means of causing secondary infections of the ear, nose and throat by the introduction of *B. friedlander* and other organisms derived from the intestinal flora. Since the universal introduction of modern aseptic technic into otolaryngologic practice, these bacteria are rarely encountered in infections of the upper respiratory tract.

The occurrence of *B. friedlander* in ozaena and rhinoscleroma is now generally regarded as a secondary invasion of no causal significance. We venture to suggest that the organism has been introduced in these cases from the intestinal tract by nose picking, a habit almost irresistible in this type of nasal trouble.

INTESTINAL TRACT

B. friedlander is commonly found in the intestinal tract. It has been isolated from the stool in some cases of enteritis (Berthelot and Bertrand,¹⁹ Jampolis, Howell, Calvin and Leventhal,²⁰ Abel,²¹ Zimmsen⁸). We have made no systematic effort to determine the frequency of the encapsulated gram-negative bacilli in the intestinal flora, but Dudgeon²² has found it in the feces of 55 per cent of normal and abnormal individuals. Kendall²³ regards *B. friedlander* as an almost constant habitant of the intestinal tract of nurslings, common in the intestinal contents of bottle fed infants and frequently present in small numbers in the adult intestinal tract.

It is, therefore, not surprising that we encountered the Friedlander bacillus most frequently in infections arising primarily from the intestinal tract. In most instances the intraabdominal infection was due to a perforative lesion of the intestine or the appendix. We are able to report 61 cases of this type. The number was limited only by the fact that cultures were usually omitted by the surgeons in intraabdominal suppurations due to perforations of the appendix or other parts of the intestinal tract.

Of the 61 instances in which the intraabdominal suppuration was apparently due to this organism, 53 were appendicitis abscesses. In 16 instances, it was associated with one or more other organisms characteristic of the intestinal flora, most frequently *B. coli*. The organism was also recovered in subphrenic collections of pus and in peritonitis of appendiceal origin, peritonitis complicating an intestinal obstruction, peritonitis due to a perforating carcinoma of the cecum, pelvic abscess secondary to a sigmoid diverticulitis with vesico-sigmoid fistula and perirectal abscess. In spite of the irregularity with which cultures were made in abdominal infections of intestinal origin, our experience indicates that *B. friedlander* is far more commonly encountered in infections arising from perforative lesions of the intestinal tract, particularly the appendix and large intestine, than in infections of any other organ.

BILIARY TRACT

Cholecystitis and Cholangitis Friedlander infections of the gall-bladder and bile passages and liver abscess due to this organism have been recorded by Carnot, Dumont and Lebert,²⁴ Brouardel,²⁵ Hegler and Nathan²⁶ and others. In contrast to the relative rarity of respiratory tract infections due to *B. friedlander*, we are able to report 46 cases of suppurative infections of the biliary tract. The pus in the infected gall-bladder or common duct is usually thin and presents no distinctive characteristics. In some instances it is thick and mucoid and has a faint foul odor. Gangrene of the gall-bladder wall and pericholecystic abscesses are observed as in other types of infection.

B. friedlander was present in the pus in pure culture in 43 of the 46 cases of cholecystitis and cholangitis. In two instances it was associated with *B. coli* and in one with *B. coli* and *B. proteus*.

Mechanical Predisposing Causes Gall stones were present in the gall-bladder or common bile duct in 38 of the 46 cases. In two other instances, the common or cystic duct was obstructed by carcinoma. It is of interest to note that *B. friedlander* infection of the gall-bladder or biliary passages occurred without any obvious predisposing cause only in six cases in the entire series. This suggests that the excretion of the organism by the liver, whenever it gains entry into the portal circulation, is usually accompanied by little danger of infection of the biliary passages—unless there is biliary stasis due to a mechanical cause such as calculus or neoplasm.

Mortality Our observations reveal a strikingly high mortality for biliary tract infections with this organism. Fourteen of the series of 46 patients died, a mortality of 30 per cent. This extremely high mortality was due in part to the unusually frequent occurrence of cholangitic and pylephlebotic liver abscesses, secondary to the infection of the gall-bladder or biliary passages.

Liver Abscess In 10 of the 14 fatal cases one or more liver abscesses were revealed by operation or necropsy. In four, the liver abscesses were due to an ascending suppurative cholangitis. Two were produced by direct extension from the infected gall-bladder or the associated pericholecystic abscesses. Four were of pylephlebotic origin. The suppurative pylephlebitis arose in three of the cases as a result of the suppuration in the gall-bladder and common bile duct. In one case, a pylephlebotic liver abscess was secondary to an acute gangrenous appendicitis. Except for this one instance, all cases of liver abscess due to *B. friedlander* developed as a result of a primary infection in the gall-bladder or biliary passages.

In five of the 10 cases, the liver suppuration gave rise to a bacteremia, a remarkably high incidence. In three of these cases, necropsy revealed that the organisms had gained access to the blood stream because of a secondary suppurative phlebitis of an hepatic vein adjacent to the abscess.

Metastatic Lung Abscesses Multiple lung abscesses were present as a

complication in three of the cases complicated by liver abscess, in two of which the blood culture was positive. One of the cases of metastatic lung abscess developed an empyema of the pleura which required thoracotomy. In a case of suppurative pyelophlebitis of the right portal vein and subphrenic abscess a pleural effusion developed in the right pleural cavity, which became infected only after transpleural aspiration of the subphrenic abscess. Thereafter, a pure culture of *B. friedlander* was obtained from the pleural cavity.

When *B. friedlander* is cultured from a lung abscess or an empyema of the pleura, the possibility must be considered that the abscess of the lung or pleura may be metastatic from a primary suppuration of the liver.

URINARY TRACT

The organism has been repeatedly described as the cause of infections of the genito-urinary tract (Chiari,²⁷ Park, Williams and Krumwiede,¹⁰ Villiere,²⁸ Bertrand-Fontaine and Pailier,²⁹ Montt-Saavedro,¹⁰ Howard,³¹ Macaigne,³² Speck,³³ Halban³⁴). In our experience the *B. friedlander* infections of the genito-urinary tract are somewhat more frequent than those of the gall-bladder, liver and biliary passages. We are able to report upon 50 infections of the urinary tract, compared with 46 cases of infection of the biliary tract. Although the *B. friedlander* is usually found in the liver and biliary tract infections in pure culture, it is more commonly observed in the infections of the kidney and the urinary passages in association with *B. coli*, *B. alkaligenes*, *B. pyocyaneus*, or the enterococcus. Like *B. friedlander*, they are derived primarily from the intestinal flora. Mixed infections with one or more of these organisms were present in 13 of the 50 cases. In one of the cases the blood as well as the urine contained both *B. coli* and *B. friedlander*.

TABLE II

Mechanical Obstruction as a Predisposing Factor in Excretory Infections with <i>B. friedlander</i>		
Biliary passages and liver	Total number of cases	46
Stones in common duct or gall-bladder		38
Neoplasm obstructing common duct		2
No obstruction		6
Urinary tract	Total number of cases	50
Stones in urinary tract		37
Obstruction due to carcinoma of the bladder		1
Obstruction due to adenoma of the prostate		2
Mixed infection in tuberculosis of kidney		2
Horseshoe kidney		1
Kinking of uretero-pelvic junction		1
No obstruction		6

Predisposing Causes. As in the biliary infections, mechanical stasis in the urinary passages was a common predisposing factor, being present in 44 of the 50 cases. Although in the biliary tract the cause of stasis was either calculi or neoplasm, in the urinary tract infections a greater variety of mechanical causes played a rôle. Urinary calculi were by far the most com-

mon contributory cause, but other factors were carcinoma of the bladder in one case, adenoma of the prostate in two, tuberculosis in two, horse shoe kidney in one and kinking of the uretero-pelvic junction in one case. Apparently the organism is excreted by the kidneys whenever it gains entry into the systemic circulation, but even under these circumstances it is not apt to cause an infection in the urinary passages unless there is urinary stasis due to a mechanical obstruction.

Mortality The mortality rate of *B. friedlander* infections of the urinary tract is lower than that of similar infections of the liver and the biliary passages. Eight of the 50 patients died of the infection, a mortality of 17 per cent, compared with a death rate of 30 per cent in our biliary series. In three of the eight patients who died, the blood culture was positive during life. However, two patients recovered who had a single positive blood culture during the course of their urinary infection and a third patient recovered although blood culture had been positive on two occasions.

FEMALE GENITAL TRACT

Uterine and tubal infections with this bacterium have been reported by Scheyer³⁵ and Howard³¹ and cases of postabortive sepsis by Reichert³⁶. Our experience is limited to five cases of suppurative salpingitis or salpingo-oophoritis complicated by pelvic abscess from which a pure culture of the organism was recovered, and to one case of recto-vaginal fistula following colpotomy. It is reasonable to believe that the infection in some of these cases spread to the uterus and adnexa from the adjacent rectum or colon. In one case of postabortive infection, the organism was probably introduced during instrumentation by contamination with fecal material.

B. FRIEDLANDER BACTEREMIAS

The literature contains many reports of cases of Friedlander bacteremia (Lenhartz,³⁷ Canon,³⁸ Clairmount,³⁹ Chiari,²⁷ Conradi,⁴⁰ Caussade, Joltrain and Surmount,⁴¹ Beco,⁴² Apelt,⁴³ Wehrsig,⁴⁴ Mason and Beattie,⁴⁵ Colombe,⁴⁶ Lereboullet and Denoyelle,⁴⁷ Lereboullet and Pierrot,⁴⁸ Breitkoff,⁴⁹ Sisson and Thompson,⁵⁰ Belk⁵¹). In Hegler and Nathan's²⁶ and Courmount, Dujol and Devic's⁵² cases, the portal of entry was an infection of the gall-bladder or bile passages, in Chiari's²⁷ case an ascending suppurative nephritis, in Conradi's⁴⁰ an umbilical vein infection and in one of Lereboullet's⁴⁸ three cases we suspect the urinary tract. In some of the reported cases, the portal of entry for the bacteremia was not ascertained during life (Abel⁵¹).

Libman⁵³ obtained positive blood cultures only three times among over 40 cases of suppurative pyelophlebitis and in one of the three instances, the bacteremia was due to *B. friedlander*. On the other hand, the organisms which he encountered most commonly in the blood stream in cases of pyelo-

nephritis arising without any antecedent manipulation in the genito-urinary tract were the colon bacillus and the Friedlander bacillus. He emphasized the fact that the latter is at times mistaken for the colon bacillus, because a proper capsule stain necessary for its identification is not employed.

Cases of *B. friedlander* bacteremia with recovery have been described by Courmont, Savy and Charlet,⁵⁴ Mitchell⁵⁵ and others. Crohn⁵⁶ reported a case of acute *B. friedlander* endocarditis, the portal of entry being a pyelitis, and Schoeppler⁵⁷ described a case of pericarditis.

We can report 16 cases of *B. friedlander* bacteremia, of which four recovered. A fifth case recovered from the bacteremia only to return to the hospital subsequently with a secondary (*B. friedlander*) osteomyelitis of a vertebra from which he died. In 14 cases the organism was present in the blood during life in pure culture, in one it was associated in the blood with *B. coli* and in another with several intestinal bacteria.

Portals of Entry. Of the 16 cases of *B. friedlander* bacteremia, six are from infections of the liver and biliary tract, six from infections of the urinary tract, one from an acute otitis media complicated by mastoiditis and suppurative meningitis, one from a postoperative meningitis probably due to fecal or skin contamination during convalescence from an operation for spinal cord neoplasm and one from an infection of the gynecological tract.

In one other case, the organism was recovered in a blood culture from a patient with aplastic anemia only two and a half days before death. The blood culture also contained colonies of *Staphylococcus albus* and *Streptococcus alpha* so that we are probably justified in concluding that this case represented a preagonal blood invasion in a patient dying slowly of a wasting and debilitating disease.

It is of particular interest to note that no case of bacteremia in our entire series had its origin in a primary lung infection and only one in the upper respiratory tract (otitis and mastoiditis). However, others have reported instances of *B. friedlander* bacteremia complicating pneumonia.

In the case of bacteremia which followed an ear infection, there was doubt (1) whether *B. friedlander* had gained access to the ear as a result of an acute nasopharyngitis and sinusitis, or (2) whether some other organism has been the primary infective agent in the otitis and the *B. friedlander* had been introduced secondarily at the time of the myringotomy, 10 days after the onset of the otitis. The mastoiditis developed four days after the myringotomy. Signs of meningitis began almost four weeks later and the patient died of this cause within another week.

BACTEREMIA COMPLICATING LIVER AND BILIARY TRACT INFECTIONS

Six cases of bacteremia were observed among 46 *B. friedlander* infections of the liver and biliary passages. Five died of the infection. One recovered and was reported to be well four months after discharge from the hospital.

It is important to note that multiple abscesses of the liver were found at necropsy in all five of the fatal cases. In two the liver abscesses were pyelephlebitic and in the other three cholangitic or cholecystic in origin. In the patient who recovered, the liver at operation seemed clinically to be normal. A cholecystitis and cholangitis was found and drainage of the gall-bladder was followed by recovery from the blood stream infection.

In three of the six cases of liver abscess with bacteremia, the organism gained access to the general circulation only after the development of a suppurative thrombophlebitis of adjacent hepatic veins.

In all six cases of bacteremia complicating liver and biliary tract infections, the organism was excreted by the kidneys and could be recovered from the urine. Five developed secondary excretory Friedlander infections of the urinary tract.

BACTEREMIA COMPLICATING INFECTIONS OF THE URINARY TRACT

In our experience, bacteremia due to *B. friedlander* arises as frequently from infections of the kidney and urinary passages as from the biliary tract. This complication occurred in six of our 50 cases of *B. friedlander* infections of the kidneys or urinary passages.

Fortunately, blood invasions from this source are often transient, so that three of our six cases recovered. In two of the recovered cases, the organism was recovered from the blood stream only on the day following a so-called urethral or ureteral chill.

In one of the three fatal *B. friedlander* bacteremias of renal origin, the blood stream infection cleared up spontaneously so that the patient was discharged from the hospital apparently cured. This is the patient previously mentioned who returned eight weeks later because of a metastatic osteomyelitis of a vertebra and died of a secondary *B. friedlander* bacteremia from this source.

BACTEREMIA FROM INTESTINAL TRACT INFECTIONS

In spite of the fact that the *B. friedlander* is a normal habitant of the intestinal tract and that it is found most commonly in pyogenic infections of the abdominal cavity due to perforative lesions of the intestines and appendix, it rarely enters the blood stream from this site. In one instance in our experience, which we have already mentioned, it entered the blood stream preagonally two and a half days before death in a patient dying of aplastic anemia.

SUMMARY

The Friedlander group of encapsulated gram-negative bacilli usually gain entry into the body from the intestinal tract. For this reason they are frequently encountered in abdominal suppurations due to perforative lesions of the appendix and the colon.

Like *B. coli* and other intestinal saprophytes *B. friedlander* may enter the systemic or the portal circulation and be excreted by the kidneys or the liver. Under these circumstances, excretory infections are apt to occur if there is stasis of urine or bile due to the presence of a calculus, a neoplasm or other mechanical factor. A predisposing mechanical factor was present in 84 of the 96 cases of excretory infections of the urinary and the biliary passages.

The mortality of *B. friedlander* infections of the abdominal viscera is high. There were eight deaths among 50 urinary tract infections (16 per cent) and 14 deaths among 46 infections of the biliary tract (30 per cent). The isolation of *B. friedlander*, especially from infected bile, is therefore of grave prognostic import.

In urinary tract infections, *B. friedlander* is often associated with *B. coli*, *B. proteus*, *B. pyocyaneus*, enterococcus or other bacteria belonging to the intestinal flora. In biliary infections this association is uncommon and the organism is usually recovered in pure culture.

B. friedlander is encountered infrequently in infections of the vagina, uterus and female adnexa, to which it may gain access by direct extension or by lymphatic or hematogenous carriage from the intestinal tract. In some instances it is probably introduced as a contamination from the adjacent rectum or anus by instrumentation or during self induction of abortion.

Primary *B. friedlander* infections of the lungs and the upper respiratory tract are clinical rarities, in comparison with the frequency of infections of the abdominal viscera.

Sixteen cases of *B. friedlander* bacteremia are reported, of which 12 developed from infections of the biliary or the urinary tract. Most of the cases of bacteremia which arose from extrarenal sites of infection developed a secondary excretory infection of the urinary tract during their clinical course. Recovery was common in the bacteremias of renal origin, and unusual in blood infections arising from the liver and biliary tract and other extrarenal sites.

CONCLUSIONS

This report of 198 *B. friedlander* infections indicates that the organism is predominantly associated with abdominal infections, especially suppurations due to perforations of the appendix and colon, and next most frequently with excretory infections of the biliary and the urinary tract. In this respect it conforms pathogenically with *B. coli* and other gram-negative bacilli of the intestinal flora. In comparison with the frequency of Friedlander infections of the abdominal viscera, infections of the respiratory tract with this organism are relatively uncommon.

It is therefore recommended that the terms *Bacillus pneumonae* and *Pneumobacillus* be abandoned because they have served to perpetuate a

wrong conception of the essential rôle of the bacillus of Friedlander in infections, and that the bacteriological designation *Klebsiella pneumoniae* be changed to *Klebsiella Friedlander*

THE BLOOD PRESSURE IN STENOSIS AT THE ISTHMUS (COARCTATION) OF THE AORTA, CASE REPORTS¹

By JOHN T. KING, F A C P, *Baltimore, Maryland*

IT is well known that the arterial pressure in the arms in cases of congenital stenosis at the isthmus of the aorta is frequently higher than the normal. This is so often the case, that the impression is more or less current that hypertension in the arms is a necessary part of the diagnostic picture, and that investigation of all cases of hypertension will lead to recognition of all cases of isthmus stenosis. Gossage²⁴ has said "No doubt in these cases the blood pressure is always high, so as to overcome the difficulty of getting the blood through the narrow arterial channels." Lewis,²⁷ referring to instances of slight constriction and to cases of coarctation complicated by cardiac embarrassment, is of the opinion that "if we note these cases as natural exceptions then it is true to state that most cases, perhaps all uncomplicated cases, of coarctation of the aorta of the adult type present high blood pressure, the statement applies to both systolic and to so-called diastolic readings."

That such views are in accord with the facts in a large proportion of the cases is readily demonstrated. My own experience is perhaps rather typical of 12 original cases which I have examined, there was an absolute hypertension in the arms in 10, the pressure was not determined in one, while in another it was normal (last case in the series herewith reported). The occasional occurrence of such findings as those in case 5, in which the pressure in the arms, while higher than that in the legs, is nevertheless within normal limits, together with some interesting findings among the cases already reported, will suggest a modification of the general opinion that the finding of hypertension affords the most important clue to isthmus stenosis.

In order to determine the significance and relative incidence of normal blood pressure in coarctation, I have reviewed the literature and have analyzed all the pressure readings that are accessible. With this analysis, I shall report briefly five heretofore unreported cases, including that of the patient with normal pressure.

The first blood pressure readings in this condition seem to have been made by Potain and Bureau²⁸ in 1892, followed in 1893 by an observation by Steiner.²¹ At the present time 170 such reports have been found.

Blood pressure reports divide themselves into four general categories. The first group consists of those cases in which hypertension was demon-

* Received for publication March 25, 1937

stated in both arms, the second group contains cases in which hypertension was reported but in which the pressure was determined from one arm only. Doubtless a number of cases of this type would have been found to have elevated pressure in both arms, had a more complete report been given, hence would have appeared in table 1. However, there is a group (table 4) in which there was a hypertension in the right arm, with normal pressure in the left because of the possibility that some cases in table 2 might have been of the same type as the cases in table 4 or table 1 if the pressure had been determined in both arms, it seems safer to leave all cases of unilateral pressure reports in a separate group (II).

Tables 1 and 2 consist of cases with the more orthodox pressure findings—a definite hypertension in one or both arms and comparatively low pressure with feeble pulsations in the legs.

Of the adult hypertensive patients in table 1 the average pressure in the right arm was found to be 190 systolic and 92 diastolic, that in the left arm 185 systolic and 94 diastolic. Such a difference has been noted in previous reports and has been thought to be due to slowing of the blood stream as it passes the mouth of the left subclavian artery, a condition due to the proximity of the coarctation to the left subclavian. The average pressures in the legs were not unlike, being 125 systolic and 93 diastolic in the right, 120 systolic and 89 diastolic in the left (table 1).

In table 4 is found a group of cases of unusual interest inasmuch as there is a marked disparity of pressure in the two arms, that of the left being within normal limits. This statement should be qualified by pointing out that there was a diastolic hypertension in the left arm in four of the 10 cases of table 4. Moreover, the case reported by East²¹ (number 5) is an exception to all rules, since the pressure is substantially higher in the left arm than in the right. As there was no autopsy, the explanation of this bizarre finding is not known.

A possible interpretation of the other nine cases of table 4 is suggested by Parkes-Weber and Knop⁷¹ in discussing the case of Turkington⁷⁰ (number 8 in this group). These authors quote D. E. Bedford, who described a case in the Museum of the Heart Hospital, London, in which there was observed a fibrotic stenosis at the origin of the left subclavian artery.

It seems probable that the cases in table 4, excepting that of East²¹ (number 5), had an isthmus stenosis complicated by involvement of the mouth of the left subclavian artery in a stenosing process. In cases of "persistent isthmus" the mouth of the artery and the isthmus might well be involved in a single anomaly.

The cases in table 3 deserve especial note, as here are 19 cases in which the arm pressure was within normal limits. I have included my own observation (case 5 in the appended series). Nine cases were substantiated by autopsy. It should be stated that no note was found in some of

CASES OF COARCTATION OF THE AORTA FROM 1892 TO 1936, WITH BLOOD PRESSURE READINGS

these reports to identify the arm from which pressure readings were taken. There are six cases without autopsies in which the pressure was noted from an unspecified arm. If such readings were taken from the left arm, a hypertension in the right might have been overlooked. Lewis⁵⁷ points out that heart failure might bring about a fall of previously elevated pressure to within normal limits in some cases. In 15 of the 19 cases in this group there seems to have been either circulatory embarrassment, or gross failure, or chronic sepsis, sufficient to have reduced a previously elevated blood pressure to normal. Blackford's⁹ patient (case 3) complained of respiratory distress, including orthopnea, but developed neither cyanosis nor edema. The patient reported by Canculescu and Missirliu¹⁴ (case 5) was a boy of 14 years, who had had a protracted illness and who came under observation with signs of serious infection, cyanosis and circulatory insufficiency.

Henn⁴¹ seems to have reported a case of coarctation in which the circulation was compensated and in which a normal arm pressure was found. His patient complained of some dyspnea and cardiac pain but the circulation

CASES OF COARCTATION OF THE AORTA FROM 1892 TO 1936, WITH BLOOD PRESSURE READINGS

Hence, there is no well defined case so far recorded in which the circulatory compensation was above suspicion and in which the pressure in both arms was found to be normal

UNREPORTED CASES

Case 1 A young white woman of 18 years was seen at the Union Memorial Hospital through the kindness of Drs. Garis and Conley. She was admitted at the hospital for a lower right quadrant pain.

Past history was essentially negative, though some mild attacks of palpitation following exercise had been experienced over the previous six months. *The physical examination* showed a rather marked exaggeration of all pulsations in the upper extremities, especially that of the innominate. There was also a well marked pulsation in the second right interspace at the sternum, thought to be due to the mammary artery. Pulsations were felt in both interscapular regions near the scapulae at the level of the spines. A pulsating vessel of the size of one's finger was felt on each side. On the left, it was about three inches in length. On the right, while definite, it was less marked. There was a rough systolic murmur in both interscapular regions,

being loudest near the first dorsal spine *Heart* The P M I was exaggerated. Presystolic gallop was heard and a soft apical systolic murmur. Cardiac dullness was a trifle full to the left, measuring 9.5 cm to the left of the midline, 4 cm to the right. *Pulse* was bounding and of good volume at the wrists, but the abdominal aorta gave no appreciable pulsation. No pulse was felt over the femoral, dorsalis pedis or posterior tibial arteries. *The blood pressure* in the left arm was 195 systolic and 130 diastolic and in the right 180 systolic and 106 diastolic. No definite determination could be made in the legs and oscillations of the blood pressure needle were almost negligible. *The electrocardiogram* Rate 110. Rhythm regular. Conduction intervals P-R 0.18 second. Left axis deviation. T-waves upright in Lead I, biphasic in II, inverted in III. The laboratory findings were as follows.

Urine Sp gr 1.018. Appearance yellow and cloudy. Acid reaction. No albumin or sugar. There were no red cells, white cells or casts, but a large number of epithelial cells were seen.

The red cell count was 4,620,000, hemoglobin 102 per cent (Sahli). The white cell count was 13,500 with 81 per cent P M N and 19 per cent lymphocytes. The stained smear showed normal red cells and platelets. One c.c. of phenolphthalein intravenously yielded 70 per cent the first hour and 5 per cent the second hour. Non-protein nitrogen was 29 mg per 100 c.c., and fasting blood sugar 140 mg per 100 c.c.

Teleroentgenogram showed erosion of the inferior margin of the posterior part of most of the ribs, with slight cardiac enlargement to the left.

Case 2 A white woman, married, aged 24, was seen at the Hospital for the Women of Maryland through the kindness of Dr. Henry M. Thomas, Jr., who had made the diagnosis of coarctation of the aorta. The patient was a primipara, admitted to the obstetrical department in May 1934 when about four months pregnant. The family history was entirely unimportant. The past history revealed that the patient had been short of breath since childhood and had noticed an occasional sense of fluttering and some pain in the precordial area. She was not permitted to take part in athletics or gymnastic work at school by a physician's order. She was first examined in 1929 and was told that she had hypertension. Examination at the time she was three months pregnant showed blood pressure 200 systolic and 100 diastolic. The urine was clear. One month before delivery, non-protein nitrogen of the blood was 24 mg per cent. In November 1934, the patient entered the hospital and after the first stage of labor, lasting 11 hours, was delivered readily by low forceps (Scanlon maneuver). The baby, a normal male, was in good condition. The puerperium was non-febrile and uncomplicated. The post partum examination showed blood pressure 160-210 systolic, 90-110 diastolic in the arm, in the legs it was 110-140 systolic, 70-80 diastolic. Dr. Thomas discovered bilateral pulsations in the back just medial to the vertebral borders of both scapulae. There was the usual systolic murmur best heard in the interscapular region.

Laboratory tests were as follows.

Urine examinations were consistently negative for sugar and albumin.

Mosenthal test showed concentration power of 0.007.

Phthalein test showed an appearance time of 5 minutes with half hour excretion of 50, 15, 10 and 5 per cents for a two hour total of 80 per cent.

Blood Wassermann was negative.

Blood chemistry on 6/19/34 non-protein nitrogen 26 mg per cent. Uric acid 24 mg per cent. Creatinine 1.3 mg per cent. A repetition showed on 10/16/34 non-protein nitrogen 24 mg per cent, uric acid 2.6 mg per cent, CO_2 combining power 61 volumes per cent. *Teleroentgenogram* Notching of the inferior rib margins. Cardiac shadow within normal limits. Defect in region of aortic knuckle in both antero-posterior and oblique views.

Remarks This patient was carefully observed during pregnancy, but was thought

to be suffering from malignant hypertension. While she was delivered without complications, she was advised to avoid further pregnancies.

Case 3 A white, single woman of 22. She was a patient at the Johns Hopkins Hospital in July 1932, complaining of high blood pressure, kidney trouble and burning on urination. Family history contained nothing of relevance. The patient had been subject to frequent headaches with dizziness. She had nocturia two or three times. The urine was quite normal. The gynecological examination was normal. The physical examination was as follows:

There was a distinct difference in the degree of pulsation in the arms as compared with the legs. The abdominal aorta was barely felt and pulsation in the femorals and dorsalis pedis was not made out. There was no history of nocturia prior to one year ago, no intermittent claudication, but she had suffered from numbness and coldness of legs requiring her to get out of bed and use oil rub the legs. On careful palpation very slight left dorsalis pedis pulsation was felt. There was mottled cyanosis of the lower legs. P. M. I. was vigorous when patient was supine. There were no shocks or thrills. Dullness was about 4 by 7½ cm. No increased retromanubrial dullness. Sounds vigorous at apex with soft systolic blow, practically absent in erect posture. Accentuation of A₂ and P₂. Systolic murmur of moderate intensity heard over root of the aorta, no diastolic, very large pulsation in episternal notch. Bilateral pulsating vessels about the size of small finger just at the inner margin of each scapula running roughly up and down. No appreciable murmur on the right side, short rough systolic murmur in left interscapular region, at about the level of the spine. Arteries of fundi very tortuous and there was definite slight pulsation of the arterial trunks. Vessels were more numerous than normal.

Teleoecentgenogram Typical rib erosions. "Chimney" shaped aortic shadow. No cardiac enlargement.

Further examination revealed chronic tonsillitis and enlarged adenoids. Basal metabolic rate was between +15 and +23 per cent, without definite signs of hyperthyroidism. Blood pressure arms 180 systolic and 102 diastolic, legs 110 systolic, and diastolic not known.

The electrocardiogram was normal. T₁ was inverted. Blood chemistry non-protein nitrogen 31 mg per cent. Phenolsulphonephthalein elimination was 65 per cent for 2 hours. Urinary concentration test showed a variation of specific gravity from 1.002 to 1.026. Only 130 c.c. of urine were passed between 7 p.m. and 7 a.m. as against 1825 during the preceding day. Blood Wassermann reaction negative.

Diagnosis Isthmus stenosis.

Case 4 A 15 year old white boy, seen by courtesy of Dr. T. B. Futcher. There was no complaint. Family history was negative. Past history tonsillectomy at two years of age. Present illness. Patient has no symptoms under ordinary circumstances. Specifically, there is no dyspnea on ordinary exertion. When running, he is conscious of shortness of breath but there is no palpitation or precordial distress. There is no edema and no nocturia.

The physical examination was negative except as noted below: the retinal arteries were distinctly tortuous but showed no A-V compression and there were no hemorrhages or exudates. There was no cardiac shock or thrill. Pulsation of dorsal scapular arteries was well felt in both interscapular areas. The radial pulses were full, bounding—the right apparently of higher tension and fuller volume than the left. No pulsation was felt in the abdominal aorta, femoral or popliteal arteries. Pulsation could barely be felt in the posterior tibial and dorsalis pedis arteries. The blood pressure in the right arm was 174 systolic and 94 diastolic, in the left arm 142 systolic and 90 diastolic, in both legs about 100 systolic and 70 diastolic. Pulse was regular, not accelerated. At the apex was heard a soft systolic murmur which disappeared on exercise. Over the base a harsh systolic murmur was heard which was trans-

mitted upward and outward on both sides. It was heard best in the two interscapular areas.

The Wassermann reaction was negative. Blood non-protein nitrogen 43 mg per cent. Red blood cells 5,020,000, hemoglobin 15.4 gm, white blood cells 5,500. Phenolsulphonephthalein kidney function test showed 75 per cent elimination in 2 hours. The urine was normal.

It is of some interest that the erosion of the under surfaces of the ribs is already apparent in the roentgenogram of this patient. The cardiovascular stripe is also of

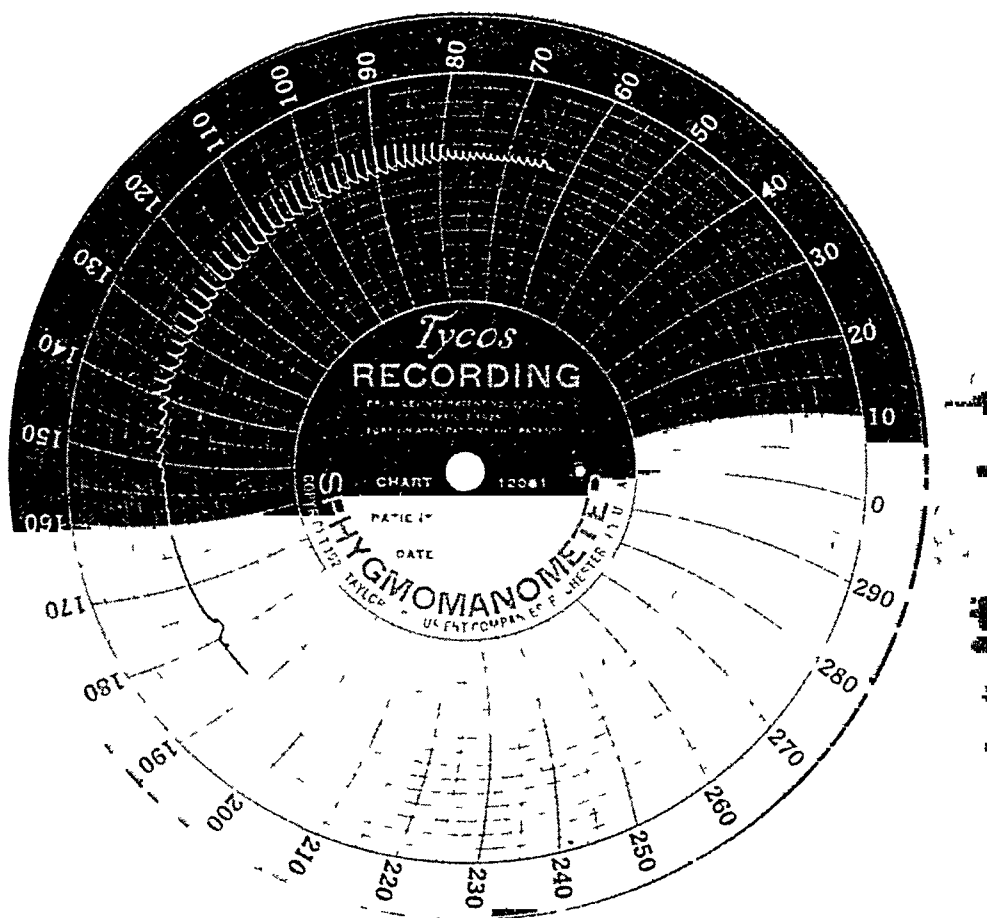

FIG 1 Record of blood pressure from right arm in case 5. Systolic level is about 138, diastolic, about 80.

typical contour. Unfortunately, there are no previous roentgenograms to indicate the age at which rib erosions became apparent. The heart was not enlarged.

Case 5. A white matron, aged 25, of Jewish extraction, consulted me in January 1929. The family history was not relevant. She had had one healthy child, no miscarriages. A second healthy child was born in 1930. There was no complication with either pregnancy.

The single persistent symptom was excruciating headache, which had tormented the patient as far back as she could remember. My impression on seeing her in 1929

was that the headaches were probably associated with the isthmus stenosis of the aorta, possibly due to actual aneurysm of the cerebral vessels. However, there was no severe headache from the time of her second pregnancy until I saw her in 1932.

The immediate symptom for which this patient consulted me was cardiac palpitation, of extrasystolic type.

The examination follows. The patient looks well but somewhat lean. Color good. Very slight increase in pulsations in the neck. Axillaries are visible but not the ulnar vessels. Eyes. Pupillary reactions normal. Transient lid-lag. Nose. Nor-

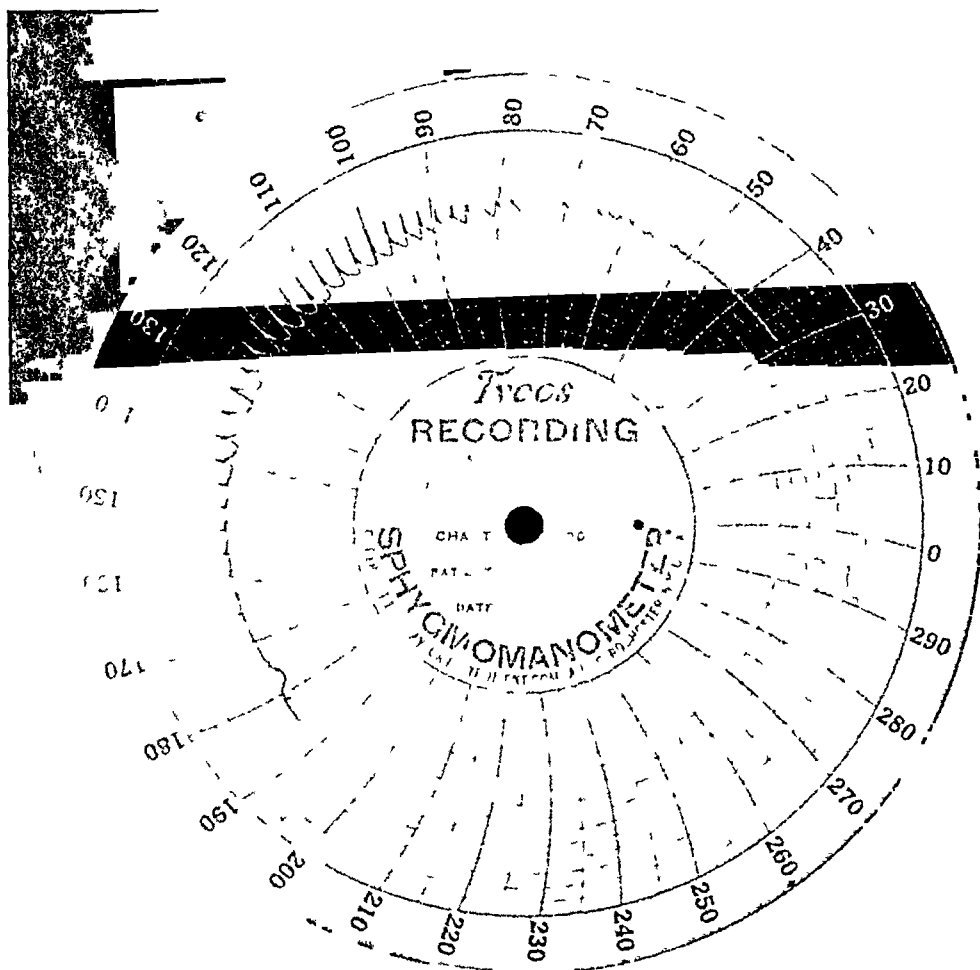

FIG 2 Blood pressure from left arm in case 5. Pressure about 123/87

mal. Mouth and throat. Quite normal. Tonsils small. Glands. Cervicals not enlarged. Thyroid. Normal. Chest. Resonant. Breath sounds normal. No retro-manubrial pulsation and no significant dullness. Back. There is a definite pulsation along the inner margin of the left scapula, but I find it difficult to outline the shape of the vessel. A similar vessel is felt in the right interscapular region. They feel like the usual collateral vessels in such cases but are smaller. There are no other collateral arteries to be felt over the back. There is a moderately intense systolic murmur in each interscapular region. A systolic murmur is heard over the entire

back of the chest to within 3 fingers-breadth of the right base and all the way to the left base. It is a little louder in the left interscapular region than anywhere else. Breath sounds everywhere normal. No râles.

Heart P M I is made out in the fourth space, in the natural position. No shock or thrill. Rather marked pulsation in the region of the pulmonary conus. Cardiac dullness right 3.5 cm, left 8.5 cm. Sounds at apex perfectly normal. There is a barely audible systolic blow. At the base both second sounds are slightly increased. There is a grating systolic murmur over the pulmonic area referred to the left clavicle.

FIG 3 Showing extreme reduction of pulsation in leg, with systolic blood pressure less than 100. Case 5

Abdomen On deep palpation a slight but definite pulsation is made out in the abdominal aorta. There is also a slight pulse to be felt in the right femoral artery but this is much reduced from normal. A similar pulsation on the left. Cecum is palpable. Liver not made out, neither is the spleen.

I can feel no pulsation in the left dorsalis pedis, nor in the right. There is a very slight pulse in the right posterior tibial and in the left.

Pulse At the wrist is big, regular. Rate 84.

Blood pressure Right arm 122 systolic and 66 diastolic at 2 30 p m (two hours after lunch which included tea Smoked a few cigarettes after lunch) Left arm 128 systolic and 66 diastolic

Blood pressure 1/30/29 Right arm 122 systolic and 60 diastolic Left arm 120 systolic and 60 diastolic

Electrocardiogram Rate 100 Rhythm regular P-waves upright and slightly notched in Leads I and II, especially in II, diphasic in III R-waves of normal sequence P-R 0.15 sec Q-R-S 0.06 sec S-T normal T-waves upright, normal
Diagnosis normal tracing

Dr. C. A. Waters' Roentgen-Ray Report "The roentgen-ray examination of the chest fails to show any erosion of the under surfaces of the ribs due to pressure from hypertrophy of the intercostal arteries. The ascending arch of the aorta looks to be a little enlarged and there is also some prominence of the innominate artery. The descending arch is not at all prominent and the heart is unusually small, the transverse diameter measuring only 10 cm divided as follows: M. R. 3 cm, M. L. 7 cm. The transverse diameter of the chest is 25 cm. There are numerous calcified glands noted, chiefly on the left side. There is no parenchymal infiltration. The apices are essentially clear. There is certainly nothing in the roentgen-ray examination to indicate coarctation of the aorta." (See figure 4.)

Diagnosis 1 Isthmus stenosis (coarctation) of the aorta

2 Extrasystolic arrhythmia

Comment The recordings of the blood pressure showed a systolic level in the right arm of about 138, with a diastolic level about 80, in the left arm the recorded pressure was 123 systolic and 87 diastolic. In the leg, the oscillations were minute and occurred between 90 and 100 mm. There was definite evidence of collateral arterial circulation in the interscapular region and a well marked systolic murmur, maximum in the left interscapular region. These findings seem to establish the diagnosis of isthmus stenosis beyond reasonable doubt, however, the relative normality of the arm pressure and the lack of rib erosions suggest that the degree of narrowing is not great. This is the only case of coarctation I have seen in which the arm pressure was within normal limits.

DISCUSSION AND CONCLUSIONS

It is clear from the tables that hypertension in the arms is the rule in cases of coarctation of the aorta. The pressure in the right arm is usually higher than that in the left and there is a group of nine cases in which this difference was so marked that the systolic pressure in the left arm was within normal limits. At the same time, it is not unusual to find a diastolic hypertension in the left arm in the face of a normal systolic level.

Mention should be made here of the numerous observations of asymmetric blood pressure in the two arms that have been noted in apparently normal individuals. For example, Korns and Guinand,⁴⁸ taking 10 mm Hg as the upper limit of normal discrepancy, found asymmetry of the brachial pressure in 22 per cent of apparently normal subjects. In this group with discrepancy in the two arms, the higher pressure existed in the right arm in three-fourths of the cases. Stieglitz and Propst⁹³ have recorded similar findings. In their cases 15.7 per cent showed asymmetric brachial pressure readings, the higher pressure in the majority of cases being found in the right arm. Various postulates, such as cervical rib, aortitis, arteriolar spasm, injury, arterio-venous aneurysm and central trophic disorders are suggested as possible causes of such discrepancy.

However, the second report shows that asymmetric readings of pressure are most to be expected at the extremes of pressure, either high or low, and that the discrepancy tends to disappear as the pressures approach normal. This observation, together with the high incidence of asymmetry reported by Korns and Guinand⁴⁸ in supposedly normal persons, suggests that such differences in the two arms are probably common among normal subjects,

especially when the pressure is determined only once. Doubtless, some of the discrepancies can be attributed to organic bases, such as cervical rib.

These findings tend to minimize the significance of such differences in brachial pressure as are recorded in table 1. It is true, however, that the inequality is rather more constant and striking among the cases of coarctation than might be expected in cases of generalized hypertension, though there can be no certainty of this until a large number of observations on the brachial pressures of hypertensive subjects becomes available. At any rate, it becomes clear that many of the discrepancies of pressure in table 1 are probably within normal limits.

Table 4 is more difficult to explain on the basis of normal variation. Korns and Guinand⁴⁸ reported a maximal difference of 38 mm Hg and an average of 14.3 mm in their group with asymmetric pressures. It is possible, even likely, that an organic basis existed to explain some of these discrepancies. The differences of pressure in table 4 are beyond the maximal systolic difference noted by Korns and Guinand⁴⁸ in all but one case, and in that case it was exactly 38 mm.

For these reasons, the presence of hypertension cannot be relied upon as a certain index to isthmus stenosis. If the pressure is taken in the left arm, a normal pressure might be found even in the presence of a marked hypertension in the right arm. Cases that have progressed to a state of cardiac failure or cases in which there has been a chronic infection or other debilitating disorder, may show a pressure in both arms that has fallen from an abnormally high level to within normal limits.

Case 5 in the present series also indicates that erosion of the ribs is not necessarily present in a typical coarctation. It is known that rib erosions may not be present in childhood, but in case 5 the patient was an adult. It is my belief that the demonstration of collateral arterial circulation is the most important single clue to the diagnosis of coarctation. It has been present in each of some 16 cases I have seen. Moreover, the incorporation of a search for collateral arterial pulsation in the interscapular region into a routine physical examination is readily achieved. The finding of typical murmurs in the back is also in my opinion a more important single clue than the level of blood pressure in the arm.

Finally, mention should be made of the fact that Lewis⁵⁷ emphasized the regularity with which hypertension could be expected in the adult variety of coarctation, provided the slighter degrees of narrowing were excepted together with those cases in which cardiac failure or protracted illness might have lowered a previously elevated pressure to within normal limits. In case 5 of this present series there is reason to believe that the degree of stenosis is not great, though a typical collateral circulation was found, together with a striking difference in the degree of pulsation and in the pressures of arms and legs. We have no way of determining whether the stenosis in this case is of the infant or adult type. The fact remains, how-

ever, that coarctation sufficient to produce characteristic physical signs and asymmetry of pressure between arms and legs may exist in an adult together with normal arm blood pressure

MASSIVE ATELECTATIC COLLAPSE OF THE LUNG COMPLICATING PNEUMOCOCCUS PNEUMONIA

By MAXWELL FINLAND, M D , *Boston, Massachusetts*, and HAROLD I L
LOVERUD, M D , *Manchester, New Hampshire*

MASSIVE atelectatic collapse of one or more lobes of the lung, occurring during the course of primary lobar pneumonia or complicating recovery from this disease, has been recognized by very few writers. In most articles dealing with pneumonia, either this complication is not mentioned at all or it is merely dismissed as a possible but exceedingly rare complication. Several reports of its occurrence in the pneumonias of infants and children have appeared during the past few years¹⁻¹⁰ but very few instances have been recorded in cases of acute lobar pneumonia in adults,¹¹⁻¹³ although it was recognized as far back as 1881, or even earlier.¹⁴

The characteristic findings of massive atelectasis involving one lobe or one lung have been recognized in the roentgenograms in 62 cases of primary pneumococcus lobar pneumonia in adults at the Boston City Hospital in the past seven years. During the same period, varying degrees of atelectasis were noted in the lungs at necropsy in 47 cases of pneumococcus pneumonia of various kinds. A number of the cases exhibited striking clinical features. It is of interest, therefore, to present briefly some illustrative cases and to review separately some of the features of the cases recognized by roentgen-ray and of those noted at autopsy.

CASES REPORTED IN THE LITERATURE

The early history of pulmonary atelectasis in relation to pneumonia is recorded in the studies of Rommelaere.¹⁵ According to this writer, Laennec encountered this condition in pneumonia with effusion, and Grisolle and Traube used the words "splenisation" and "carnification" which they considered to represent different types of inflammation. Rommelaere described most of the physical signs and anatomical findings in atelectasis occurring during pneumonia and emphasized the presence of mucoid sputum and the lack of displacement of the cardiac impulse in differentiating this condition from pleural fluid. He also noted that bronchophony and bronchial breathing may be present in some cases while in others the breath sounds may be entirely absent. He believed that the collapse occurred only outside the

This study was aided, in part, by a grant given in honor of Francis Weld Peabody by the Ella Sachs Plotz Foundation

inflamed portion of the lung and that the sudden appearance of this collapse may be the cause of death in some cases. He described two such cases, one was diagnosed by the failure to obtain fluid by thoracentesis and the second, which occurred during an otherwise uneventful convalescence three weeks after the onset of typical lobar pneumonia, was diagnosed by physical signs and confirmed at autopsy.

Recent interest in massive collapse of the lung dates from two important groups of observations made by Wm. Pasteur, the first relating to collapse of the lower lobes occurring in cases of diphtheria and ascribed to paralysis of the diaphragm³² and the other to a similar condition occurring after abdominal operations and considered by him to be due to reflex inhibition of diaphragmatic movement³³. The condition has since been frequently recognized and described as a complication in a variety of conditions including (1) surgical operations, (2) trauma to the chest or elsewhere, (3) after hemoptysis in pulmonary tuberculosis, (4) in cases of bronchiectasis, (5) obstruction of bronchi due to foreign bodies or tumors, or (6) from pressure outside the bronchus, and (7) in nervous and debilitated individuals with pulmonary hypoventilation. An extensive bibliography is included in a recent paper by Bowen³⁴. Inasmuch as the primary interest in the present paper concerns atelectasis as a complication of pneumonia, only the literature pertaining directly to this subject will be cited.

As previously noted, massive atelectasis indicated by a shift of the mediastinal contents to the affected side, has been encountered more often in the pneumonias of infants and children. Thoenes¹ reported 11 cases in which this condition was definitely demonstrated in the roentgenograms. Most of his children were undernourished and had atypical pneumonias, but cases of typical unilateral lobar pneumonia in previously healthy children were also included. One or more lobes of the right lung were affected in 10 of his 11 cases, the upper lobe being most frequently involved. There were autopsies in four of these cases. In two the heart had returned to a normal position, in one there was partial atelectasis and in the fourth massive collapse with the mediastinum pulled over to the affected side. Wallgren² reported eight cases in children ranging in age from six months to nine years. The involvement was right-sided in three and left-sided in five, and probably began during acute pneumonia. Some of his cases may have had the atelectasis at the time of the onset of the pneumonia. All had cleared after intervals varying from a few weeks to a year. Griffith³ criticized the observations of the last two authors mainly on technical grounds. However, in careful roentgen studies in 40 cases of pneumonia in young children, he noted definite and sometimes marked displacement of the heart to the affected side with subsequent return to normal position in 16 cases with unilateral involvement, but did not make sufficient observations to determine when this condition began or how long it lasted. Although admitting that atelectatic patches in the consolidated lung might aid the displacement, this writer ascribed the condition to overdilatation of the unaffected lung. Tal-

lerman and Jupe⁴ described a similar occurrence in five children, including three with lobar pneumonia and two with bronchopneumonia, in all of whom the condition cleared completely. In one of their cases there was pneumonia with atelectasis on the right side which cleared at the time when the left lung became involved with pneumonia but without atelectasis. They considered the cardiac displacement due to both the partial collapse of the affected lung and the push of the sound overdistended lung. Findlay⁵ reported the case of a child of seven who, when first seen one, possibly two weeks after the onset of a pneumonia, was afebrile but had much mucopurulent sputum. Partial collapse of the left lower lobe was noted by physical and roentgen examination. He noted bronchial breathing and increased spoken voice at some examinations and absent breath sounds at others. The condition cleared completely in 2½ weeks after a roentgen-ray examination with lipiodal, followed by carbon dioxide inhalations. Gleich⁶ reported a case of lobar pneumonia of the right lung in a child with complete situs transversus in whom the physical signs alternated between those of atelectasis and those of consolidation for six weeks. Ellis⁷ reported eight cases of atelectatic bronchiectasis in children. In five of his cases there was a typical history of pneumonia in which the symptoms persisted for an unusually long time and bronchiectasis with atelectasis was present when they were first seen five or more years later. A sixth case had a typical right lower lobe pneumonia with fever for 16 days. On the thirty-third day collapse of the right lower lobe was diagnosed by roentgen-ray on the basis of a dense triangular shadow in the cardio-hepatic angle. This cleared up completely with breathing exercises in two months, and no bronchiectasis developed. Nordgren⁸ reported the case of a girl of 14 years, with a long asthmatic history, in whom massive atelectasis with induration and scoliosis developed in the right lower lobe one month after the onset of typical lobar pneumonia in this lobe, and in whom the lungs were entirely clear one month later. He ascribed the atelectasis to occlusion of bronchi with pneumonic exudate. Anspach⁹ studied 50 cases presenting, by roentgen-ray, a triangular shadow at the base of the lung in the cardio-hepatic angle, both with and without bronchiectasis. Some of these cases had bronchopneumonia without foreign bodies in the bronchi at autopsy. Some later developed bronchiectasis, while others cleared without developing bronchiectasis. The commonest history was that of an acute pulmonary process with physical signs of lobar pneumonia followed by decreased breath sounds. In 41 cases there was pneumonia with collapse. He ascribed the collapse to obstruction by pneumonic exudate, the bronchiectasis developing if the atelectasis persists. Blanton and Morgan¹⁰ reported the sudden onset of massive atelectasis of the right lung in a five weeks old infant on the ninth day after the onset of a pneumonia of the right lower lobe and three days after the fever had subsided. This infant had paroxysms of cough followed by vomiting, the vomitus containing sticky

mucus Within a week there was patchy aeration of the lung and the heart returned to normal position after one month

Fewer instances of this complication have been noted in the pneumonias of adults Gwynn¹² reported two cases in elderly patients with typical lobar pneumonia of the right lower lobe, who had a sudden episode of extreme dyspnea lasting several hours, after which massive collapse of the right lung with the heart markedly displaced to that side was demonstrated clinically In the first patient the collapse occurred on the nineteenth day of illness during an otherwise uncomplicated convalescence with resolution, and in the second it occurred on the fourth day of an acute illness during which there was much mucoid sputum A third patient, who had bronchitis or bronchopneumonia of the left lower lobe, also had a similar episode with collapse of the entire left lung In each of these cases, the heart returned to normal position in five to seven days Peppard¹³ reported four cases in which collapse occurred in the right lung 10, 8, 6, and 2 days, respectively, after the onset of pneumonia, the lungs previously being noted as having pneumonia without collapse In three of these cases there was typical lobar pneumonia and the left side was later involved without evidence of atelectasis The fourth patient was described as having bronchopneumonia and the collapse cleared in three days, whereas in the other three cases it cleared more slowly Jacobaeus¹⁴ reported a case of lobar pneumonia of the right upper lobe in which collapse suddenly occurred on the eighteenth day and gradually cleared within six months The location of the lesion and the delay in clearing suggested pulmonary tuberculosis but this was ruled out by repeated negative sputum examination and by the subsequent course A second patient had central pneumonia and developed collapse of the right lower lobe Jacobaeus¹⁵ also reported a case of acute bronchitis with scattered râles, but more on the left side On the third day of illness this patient had an attack of dyspnea which was found to be associated with massive collapse of the left lung and a shift of the mediastinal contents to that side The condition had cleared completely three weeks later Mohler¹⁶ reported two cases The first had marked dyspnea following a vomiting spell, and collapse of the right lung was demonstrated six hours later The patient had slight fever but no leukocytosis and cleared rapidly and completely The second case had typical pneumonia of the right upper and middle lobes and auricular fibrillation The pneumonia was apparently clearing on the sixth day but the patient was raising thick tenacious sputum On the ninth day there was evidence of collapse of these lobes by physical examination and in the roentgenogram Corrylos and Birnbaum^{17, 18, 19} presented extensive experimental evidence and some clinical data to support their contention that lobar pneumonia is merely a lobar atelectasis with infection They advocated bronchoscopic aspirations, while Henderson²⁰ advocated carbon dioxide inhalations for treatment early in the disease Manzer²¹ reported two cases in which typical collapse of the lung was

rapidly relieved by bronchoscopic aspiration of gelatinous material. The condition was ushered in with chill and fever, in each case. Wu²² and Graeser, Wu and Robertson²³ reported a careful study of the roentgenographic findings and physical signs in 40 cases of lobar pneumonia in adults. Elevated diaphragm on the affected side was noted in 18 cases. In four cases they observed a definite shift of the mediastinal contents to the affected side during resolution. This was especially marked in one case in which it lasted at least 29 days but the lungs had returned to normal in two months. There were three other cases with slight but definite atelectasis during the acute disease, and they have observed another more striking case outside the series in which the collapse was noted on the second day of illness. Two of the cases died three to four days after the last observation, and the mediastinal contents were found at autopsy to be in normal position. Hart²⁴ noted that displacement of the heart, trachea, and diaphragm to the affected side is common in pneumonia. Korol²⁵ suggested roentgenograms in suitable positions to differentiate empyema from large areas of atelectasis in cases with prolonged signs and symptoms. Rigler²⁶ presented the roentgenograms of a rare case, in which the entire right lung was dense but the mediastinum was in normal position on the fifth day, but in which after an acute attack of dyspnea and cyanosis 12 hours later, the heart and trachea were shown to be definitely displaced to the right, indicating a superimposed atelectasis. Sante²⁷ also mentions this complication as a rare occurrence during resolution with rapid absorption of pneumonic exudate without removal of the material obstructing the bronchi. Davidson and Freedman²⁸ reported a case of atelectasis and fibrosis of the left lower lobe which presumably began as a collapse complicating pneumonia 25 years previously, when the pulmonary symptoms began. Fletcher and Dimson²⁹ reported a case of pneumonia of the left lower lobe in which atelectasis was first demonstrated on the eleventh and again on the twenty-first day after the onset of pneumonia, but was shown to have cleared entirely four months later. Mayoral³⁰ included among his cases of "shrunk lung" two in which the condition was attributable to lobar pneumonia. One had an earlier history of pneumonia and presented atelectasis of the right lower lobe with the heart displaced to that side. Biopsy of the partly occluded bronchus showed only fibrosis. The other case had a prolonged convalescence from pneumonia of the right lung without atelectasis demonstrable in the first roentgenogram. A second roentgenogram 20 days later and a third, six weeks after that, showed fibrosis and unresolved pneumonia with atelectasis and the heart was displaced to the right. Butler³¹ reported a case of post-pneumonic empyema associated with atelectasis in which there was poor healing and failure of the cavity to close although there was no air in the pleural cavity. In the roentgenogram the underlying lung looked dense, suggesting carcinoma. Bronchoscopy showed stenosis of the major bronchus without foreign body, tumor, or exudate. Rapid improvement

followed this procedure and later no collapse could be demonstrated in the bronchus

CASES FROM THE BOSTON CITY HOSPITAL

Many cases of pneumonia have been encountered in which repeated examinations revealed physical signs over the affected lobes alternating between those suggestive of fluid and those indicative of frank consolidation. This has occurred during the acute illness or at various stages during an otherwise uneventful convalescence. In a number of such cases, evidence indicating varying degrees of atelectatic collapse of the lung may be obtained by carefully noting the position of the heart, trachea, and diaphragm at each of the examinations. The signs of atelectasis can not always be verified by the roentgenogram unless it is ascertained that the characteristic signs are present immediately before and after the film is taken and necessary precautions in technic are observed to avoid distortion and to maintain comparable perspective in successive films. When massive atelectasis involves an entire lobe—either one that was previously uninvolved, or a partially consolidated lobe, or one in which resolution has already progressed to the point where a good proportion of the exudate has been removed or absorbed from the alveoli—the physical and roentgen-ray signs are easy to discern provided that this condition is borne in mind.

In the present study, two groups of cases will be considered. The first group includes cases in which the clinical and roentgenographic evidence of frank lobar pneumonia was unmistakable and specific types of pneumococci³⁵ were obtained from the sputum or blood, or both. Cases following operations, parturition, and injuries were excluded. Inasmuch as the physical signs and even roentgen-ray findings of minor degrees of atelectasis in acutely ill patients are not always convincing unless special precautions and technics are employed,^{23, 36} only those cases in which obvious massive collapse of one or more lobes was observed in the roentgenograms were selected. Sixty-two cases observed between 1929 and 1936 are included in this group. Certain features of these cases are analyzed in table 1. The second group comprises 47 cases of pneumococcus pneumonia (both lobar and atypical) in which atelectasis of various degrees was made out at autopsy. In each instance, type-specific pneumococci were cultured from the consolidated lung and other sources at autopsy and, in almost every instance, the same type pneumococcus was obtained during life. Although one or more roentgenograms were made in most of these cases, atelectasis was not definitely diagnosed from these films. These two groups of cases will be considered briefly and abstracts of a few cases selected to illustrate certain clinical features will be presented. A considerable number of cases not included in these two groups exhibited roentgen-ray evidence of moderate to marked elevation of the diaphragm on the affected side without shift of the mediastinal contents. Since it is reasonable to assume that this con-

dition may result solely from reflex inhibition of diaphragmatic movement, these cases have been omitted although some may indeed represent cases of massive collapse

Cases Showing Massive Atelectasis in Roentgenograms (Table 1)
The collapse was first made out during the acute disease in 34 of the 62

† Including 2 serum treated

‡ Including 2 serum treated

cases In three of these cases, previous films showed pneumonia without evidence of collapse, in the remaining cases the collapse was noted in the first film Later films showed the return of the mediastinal contents to normal position in 15 of these cases In most of the other cases no later

films were taken because of the favorable and apparently uncomplicated convalescence or because death ensued. One case showing atelectasis on the first day still showed the mediastinal contents deviated to the affected right side 12 days later.

Six of these 34 patients died, and autopsies done in four failed to show atelectasis. In one of these autopsied cases there was organizing pneumonia in the right lung. This lung had been shown by roentgen-ray to be collapsed 24 days before death, but not 16 days later. In the other three autopsied cases, death occurred on the fifth, eighth and ninth day of illness or four, five, and four days, respectively, after the atelectasis was demonstrated by roentgen-ray. Of the two patients who died and had no autopsy, one had a second roentgenogram showing the mediastinum in normal position and in the other the atelectasis was demonstrated on the day of death.

Fluid was demonstrated by thoracentesis in four of the surviving cases at the time when the mediastinum was deviated to the affected side. In two instances this fluid was sterile and resorbed spontaneously, and in the other two it was infected and required treatment by open thoracotomy and rib resection.

There were 28 cases in which the collapse was first made out in roentgenograms taken after the fever and acute symptoms of pneumonia had subsided. In 21 of these cases, previous roentgen-ray films showed the characteristic findings of lobar pneumonia but no evidence of mediastinal displacement. In the remaining seven cases no previous roentgen observations were available. Subsequent roentgen-ray films showed that the mediastinal contents had returned to their normal position in 13 cases before the patient left the hospital. In most of the remaining cases either the collapse was still present or no further observations were available during the patient's stay in the hospital. Observations were made in four patients for three to 27 months after they left the hospital. In all of these four patients, the mediastinal contents were displaced to the affected side at the time of discharge from the hospital but, in three of these cases, they had returned to normal position at the time of the last observation. The day of the disease when collapse was first noted, the lobes involved, the age of the patients, and the pneumococcus types in these cases are summarized in table 1.

*Cases of Pneumonia with Atelectasis at Autopsy** Some of the more relevant features of these cases are analyzed in table 2. The 47 cases of this group occurred among 684 cases of pneumococcus pneumonia in which autopsies were done at the Mallory Institute of Pathology of the Boston City Hospital during the seven years ending July 1936³⁷. As in the first group, cases occurring after operations, parturition, and injuries were omitted. No definite evidence of collapse was noted during life in any of these cases except in the two cases of bronchogenic carcinoma. It is ap-

*We are indebted to Dr. Frederick Parker, Jr., for permission to use the autopsy protocols.

TABLE II

Certain Features of 47 Cases of *Pneumococcus* Pneumonia in Which Pulmonary Atelectasis Was Found at Autopsy

	Number of Cases
A Probably congenital atelectasis	1
(a) Infant, aged 4 days, bronchopneumonia, Type XI	
B Atelectasis probably due to obstruction	4
(a) Carcinoma of bronchus, 2 cases of bronchopneumonia (Types I and VI)	
(b) Inhaled food and bronchopneumonia, 2 cases	
(1) Infant, aged 2 days, Type XIX	
(2) Perforated esophagus, age 30 years, Type VI	
C Atelectasis associated with compression from pleural fluid	13
(a) Types I, 5, V, 2, III, IV, XI, XII, XIII and XVIII, 1 each	
(b) Ages Newborn, 1, 12 to 29 yrs, 3, 40 to 49 yrs, 3, 50 to 59 yrs, 3, 60 to 69 yrs, 2, 70+ years, 1	
D Partial or scattered atelectatic collapse	13
(a) Bronchopneumonia, 4, Lobar pneumonia, 9	
(b) Resolution and organization in collapsed lobe, 6	
(c) Hypostatic (?)—involving postero-inferior portions, 4	
(d) Early pneumonia in the collapsed lobe—extension, 2	
(e) Atelectasis only in consolidated lobes, 6, only in non-consolidated lung, 5, in consolidated and non consolidated lobes, 2	
(f) Types I, 1, II, 2, III, 1, IV, 2, V, 2, XII, 2, VIII, IX, XVIII, 1 each	
(g) Ages 2 mos, 1, 2 yrs, 1, 40 to 49 yrs, 4, 50 to 59 yrs, 5, 60 to 69 yrs, 1, 70+ yrs, 1	
(h) Duration of illness 10 days, 4, 11 to 15 days, 2, 20+ days, 5, unknown, 2	
E Massive atelectatic collapse	16
(a) Bronchopneumonia, 4, Lobar pneumonia, 12	
(b) Resolutive	
(c) Collapse lobe only, 4, Collapse bc only, 11, Collapse of consolidated and uninvolved lung, 1	
(d) Lobes collapsed Rt upper, 1, Rt middle, 2, Rt lower, 4, Rt upper and middle, 2, Rt middle and lower, 3, Left lower, 3, Left lung, 1	
(e) Types I, 5, II, 2, III, 2, V, 4, VI, 1, VII, 1, XIV, 1	
(f) Ages 5 mos, 1, 30 to 49 yrs, 3, 50 to 59 yrs, 4, 60 to 69 yrs, 2, 70+ yrs, 6	
(g) Duration of illness 9 days or less, 9, 10 to 21 days, 4, 30+ days, 3	

parent from the table that several varieties of atelectasis are represented among the cases of both lobar and atypical pneumonia

There was an impressive number of cases in which large portions of the lung were collapsed. In many instances the collapsed portions showed only slight congestion without inflammatory changes while in others there was evidence of resolution and organization with a comparatively small amount of residual exudate. It is not unlikely that acute collapse of such extent may have been the chief cause of death or a major contributing factor in the outcome in some of these patients who had already been suffering from reduced aeration due to the inflammatory consolidation in other lobes.

Abstracts of Cases It is of interest to mention briefly a few cases selected to illustrate special features of atelectasis complicating pneumonia

Case 1 Sudden and violent onset of massive atelectasis during the stage of resolution T. K., a 48 year old man, whose previous history was non-contributory except for a mild illness suggesting "pleurisy" early in 1928, was admitted to the hospital January 18, 1929. On January 1 he had coryza and a dry cough. This lasted one week and was followed by mild diarrhea, malaise, anorexia and headache lasting

another week On January 15 he had a severe chill followed by sharp pain in the left chest and cough productive of tenacious bloody and later rusty sputum, all of which continued to the time of admission The physical findings were those of lobar pneumonia of the left lower lobe Sputum and blood culture yielded Type I pneumococci Felton's Type I concentrated antibody was given intravenously in small divided doses during the first four days (total of 45 c c) Although the consolidation had spread to involve the entire left lung, there was a gradual subsidence of fever and discomfort Daily blood cultures after serum therapy remained sterile The physical signs of resolution were present throughout the left lung on January 24, but the patient remained markedly prostrated During the night of January 31, the patient was suddenly awakened with intense dyspnea and restlessness, and the pain in the left chest which had previously subsided, recurred with increased severity These symptoms subsided within a half hour after an injection of morphine A few hours after this episode the characteristic physical signs of massive collapse of the left lung were present The breath sounds in the left infraclavicular region were amphoric in character There was copious mucopurulent sputum Evidence of resolution returned but the displacement of the trachea and heart to the left side persisted during the patient's stay in the hospital They were less marked at the time of discharge on March 13, 1929 This patient's course was further complicated by a phlebitis of the left femoral vein accompanied by a low-grade fever beginning February 5 and lasting for two weeks Numerous sputum examinations during and after the acute illness failed to show tubercle bacilli The patient was examined one year later, at which time no abnormal signs were made out in the chest The patient had been symptomless during the intervening 15 months

A roentgenogram taken on January 19 showed mottled cloudiness of the lower two-thirds of the left chest with the heart and trachea in normal position Seven films taken at intervals after the attack of acute dyspnea showed the trachea and heart markedly displaced to the left, but those taken before discharge showed definite clearing especially in the lower lobe A film taken in June 1930 showed the trachea and heart in normal position and the lung fields normal

Case 2 Latent onset of massive collapse during a severe infection—delayed resolution, and fibrosis of collapsed lung M W, a 52 year old man, entered the hospital November 12, 1930, with the typical history and physical findings of a severe lobar pneumonia of six days' duration and involving the entire right lung An upper respiratory tract infection was present for one week prior to the onset Type I pneumococci were obtained from sputum and blood culture Large amounts of concentrated antipneumococcus serum were given between November 14 and 20 Repeated blood cultures were positive until November 16 but later ones were sterile The jaundice, cyanosis, distention, and physical signs of consolidation present on admission continued until November 25 Staphylococcus abscesses and decubitus ulcers developed over the thighs during this time Thereafter, there was gradual improvement but marked prostration and weakness persisted On November 21 the physical signs of atelectasis were made out and the trachea and heart were markedly displaced to the right These signs persisted until the time of discharge, February 10, but much moisture appeared in the affected lung and the lower lobe showed marked clearing Bronchoscopy was done by Dr L M Freedman on two occasions, during which much mucopurulent material was removed and attempts were made to inflate the lungs, but the collapse remained The sputum was repeatedly searched for tubercle bacilli but none were found The patient returned to the hospital six weeks later and another series of four bronchoscopic aspirations and lipiodal injections was done over a period of several weeks The lower lobe cleared completely but the upper lobe remained contracted and showed definite evidence of fibrosis The lipiodal failed to enter the bronchi of the upper lobe.

Fig 1

Fig 2

Figs 1 and 2 Roentgenograms in case 2 showing massive pneumonia of the right lung on the sixth day, and retraction of heart and trachea and clearing lower lobe on the thirty-first day

Fig 3

Fig 4

Figs 3 and 4 Roentgenograms taken one and two months respectively after the film in figure 2. Note the high right diaphragm with the heart and trachea on the right in figure 3. There is partial restoration of the heart with evidence of fibrosis in the right upper lung in figure 4 (taken after the sixth bronchoscopy and lipiodal injection).

The first roentgen-ray taken on the day of the earlier admission showed a dense right lung with the heart and trachea in normal position. The next plate taken four days later and numerous roentgen-ray plates taken during the subsequent four months showed the mediastinal contents still displaced to the left, but the later films showed that the lower and middle lobes had cleared and the bronchi to these lobes were outlined by the lipiodal which failed to enter the bronchi of the upper lobe (figures 1 to 4).

Case 3 Latent onset of massive collapse in a patient with pneumonia of moderate severity C. J., a 38 year old male, entered the hospital February 11, 1931, with typical lobar pneumonia of four days' duration involving the right lower lobe. He had had a cold and slight cough for four weeks previously. The sputum showed pneumococci which failed to agglutinate with the available antipneumococcus serums, Types I to XX, inclusive, and repeated blood cultures showed no growth. The patient had a mild illness with crisis February 18 after which time the physical signs of resolution alternated with those of fluid in the left lower lobe. During the first week in April the lung cleared almost completely. There was a moderate amount of mucopurulent sputum. Roentgenograms taken on February 12, 15, 18, and 24 and on March 2 all showed pneumonia of the right lower lobe. In the two latter plates the density was quite marked suggesting the presence of fluid. Films taken on March 8, 15, 19 and 30 all showed a markedly elevated right diaphragm, the heart displaced to the right, and the rib spaces on the right contracted but the trachea was not much displaced. A film taken on June 15 showed definite but incomplete clearing of the lung and the heart restored to normal position (figures 5 to 8).

Case 4 Pneumonia complicated by atelectasis and empyema M. N., a 34 year old woman with a negative respiratory history except for influenza in 1918, entered the hospital May 20, 1930, at the end of the fourth day of a severe lobar pneumonia involving the entire right lung. Type I pneumococci were found in the sputum and blood culture. The patient received large amounts of specific antipneumococcus serum for four days during which the initial toxemia and dyspnea gradually subsided but sweating, prostration, marked leukocytosis, and the physical signs of fluid appeared and persisted. Later examinations showed the trachea to be markedly displaced to the right and loud amphoric breathing was heard in the right infraclavicular region. The subsequent appearance of coarse moist râles in this area suggested the presence of pulmonary tuberculosis with cavitation. Numerous examinations of the sputum for tubercle bacilli were negative. A roentgenogram taken May 21 showed a dense right lung but the trachea and heart were not displaced. A subsequent plate taken on May 27 and several later ones showed marked atelectasis of the right upper lobe with retraction of the trachea to that side. Signs of resolution appeared in the upper lobe which remained collapsed throughout the 12 weeks' stay in the hospital. She had rib resection and drainage, and the wound healed completely. The patient returned after 18 months at which time no physical or roentgenologic signs of collapse could be demonstrated and the lungs were entirely clear.

COMMENT

No attempt has been made to estimate the frequency with which atelectasis complicates the course of pneumonia. The careful studies of Griffith³ and of Graeser, Wu and Robertson²³ in small groups of cases would indicate that this complication is not infrequent. The cases reported in this paper by no means represent all of the cases of pneumonia in which the condition has occurred in this hospital, but have been selected only because of the definite involvement shown in the roentgenograms or because the condition was noted at autopsy. Minor degrees of atelectasis probably occur at various

stages in most cases of pneumonia but they probably are of no significance because they are usually temporary and not extensive

The pathogenesis of this condition can be reasonably explained in the light of the present knowledge of the various mechanisms which may bring about collapse of the lung under a variety of conditions. Contraction of the partly consolidated lung early in the disease or of the partly resolved lung later is aided by the occlusion of bronchi with the unexpelled thick exudate, by the reflex inhibition of diaphragmatic movement due to the fibrinous pleuritis and is probably aided by the push of the overdistended normal lung from the opposite side. The shallow breathing during the acute illness which is common during the active disease and which is continued during the subsequent period of prostration is another factor pointed out by Goldite³⁸ and others. In other words, most of the various mechanisms suggested by previous writers may be operative in different individuals or in the same case.

Another possibility suggests itself, namely that previous damage to the lung has resulted in a loss of the normal resiliency and thus predisposes to atelectasis when pneumonia occurs. In the present cases 44 per cent of the patients with collapse gave a previous history of pneumonia, and a history of probable previous pulmonary infection was present in a considerable proportion of the cases reported in the literature, even among those in infants and children. In 1000 consecutive cases of pneumococcus pneumonia in this hospital, a previous history was elicited in only 16.5 per cent³⁹ and a similar frequency of previous pneumonias has been noted by others. It would seem, therefore, that a previous history of pneumonia is more common among those cases complicated by collapse than would be expected. In addition, there were two patients among those included in this study in whose sputum tubercle bacilli were demonstrated during the acute pneumonia, but could not be demonstrated later. Both of these patients recovered and their lungs were apparently normal to physical examination and roentgen-ray except for a slight right apical fibrosis in one of them. Furthermore, in the cases presented in this paper and in those quoted, the right lung, and particularly the right upper lobe, was affected in far more than the usual proportion of cases. This circumstance and the fact that even in many of the cases in children reported in the literature there was a history indicating previous lung infection and the fact that lobes undergoing organization have become collapsed makes this a plausible contributory factor.

Jacobaeus, Lelandi, and Westermarck⁴⁰ have suggested another possible mechanism for the production of sudden massive atelectasis, namely a spontaneous spasm and contraction of a bronchus. They noticed appearance of massive collapse of a lobe within 10 minutes after lipiodal injections in certain normal individuals and explained it in this manner. Such a mechanism may be operative in pneumonia.

The cases reported in the literature and those presented here suggest that

atelectasis of the lung may be a frequent complication of primary pneumonia and may serve to explain unusual events or puzzling physical signs or a protracted course in otherwise uncomplicated cases. It may serve to explain the suppression of breath sounds early in the disease and later may be responsible for the signs often interpreted as resulting from thickened pleura or small amounts of fluid in the pleural cavity which cannot be verified by thoracentesis. It may be an important factor in the conditions variously known as unresolved pneumonia, delayed resolution, or organizing pneumonia and contribute to a delay in healing of empyema cavities. The condition may also serve to explain certain sudden episodes of acute dyspnea and sudden deaths occurring during the course of pneumonia or during the stage of resolution. In some instances such sudden deaths may be attributable to pulmonary infarction, a condition not infrequently seen at autopsy. Indeed, in case 1 this possibility is strongly suggested by the later appearance of phlebitis of the femoral vein. The failure of this patient to raise bloody sputum, the appearance of the characteristic physical and roentgenologic signs and the fact that the first evidence of phlebitis appeared only several days later make infarction a less likely explanation of the episode of dyspnea. Furthermore, in none of the cases showing massive atelectasis at autopsy was there evidence of pulmonary infarction.

There is no suggestion from the present cases or from those reported in the literature that atelectasis is an important factor in the pathogenesis of primary pneumococcus lobar pneumonia except possibly in certain cases where the onset of the disease occurs shortly after inhalation of foreign substances such as may occur after a vomiting spell. Such an assumption is not consistent with the definite occurrence of atelectasis during the disease and after the consolidation has already involved part or all of a lobe. The studies of Robertson and his coworkers also fail to uphold such an assumption either in the spontaneous disease in man²³ or in the experimental infection in dogs.⁴¹

SUMMARY AND CONCLUSIONS

- 1 A number of cases of massive atelectatic collapse of the lung complicating primary pneumonia were collected from the literature.

- 2 A group of 62 cases of primary pneumococcus lobar pneumonia in which this complication was noted in roentgenograms was presented.

- 3 A second group of 47 cases of pneumococcus pneumonias in which atelectasis of varying extent and due to a variety of factors was present at autopsy was also considered.

- 4 The significance of this complication was discussed.

- 5 The possibility of atelectasis should be borne in mind in cases of lobar pneumonia and may serve to explain certain otherwise puzzling physical findings, sudden attacks of dyspnea or an unusually protracted course.

- 6 The usual course of events in the characteristic case where the atelectasis complicates convalescence is somewhat as follows. A patient is acutely

ill with typical lobar pneumonia and begins to show gradual evidence of improvement, with lowering of fever and pulse rate and the appearance of moisture in the consolidated lobe indicating resolution. He is suddenly seized with intense dyspnea of short duration after which pleuritic pain, moderate fever, and leukocytosis recur, and the physical signs and roentgen-ray give evidence of elevation of the diaphragm with a shift of the heart, and usually the trachea also, to the affected side. The consolidated lobe may then show signs suggesting fluid or these signs alternating with those of solidification. When the upper lobe is collapsed, the breath sounds are intense and amphoric in character and, as moisture appears, suggest tuberculosis with cavitation. These signs may be present while fluid accumulates in the pleural cavity. The collapsed lobe reexpands within a few days or weeks but organization and fibrosis may leave this affected lobe contracted.

In certain patients, particularly if they are markedly prostrated after a severe course, the signs of collapse may appear during convalescence without an explosive onset.

Collapse of varying degrees occurring during the acute stage of pneumonia may be manifested only by the signs suggesting fluid or by the evidence of displacement of the heart and trachea, or only by careful roentgenographic examination. In such cases the collapse, if it involves the affected lobe, is usually of short duration, evidence of solidification soon appears, and the course of the disease continues. If a previously uninvolved lobe is collapsed, the disease may extend to involve this lobe.

THE EXOCRINE FUNCTIONS OF THE PANCREAS

By CHARLES W. McCLURE,[†] M.D., *Boston, Massachusetts*

EARLY in my career, interest in medical research problems was aroused through a fortunate association with Dr. Joseph H. Pratt of Boston. It was he who stimulated my investigations on the normal and the pathologic physiology of external pancreatic functions. The results of these investigations furnish the subject matter of the present dissertation.

Important studies on the rôle of the pancreas in digestion began with the work of Claude Bernard,¹ who showed that the pancreatic juice was essential to the process of digestion. Other physiologists of that time were, however, unable to confirm Bernard's observations,² and although many further careful investigations of the digestive function of the pancreas were reported by various observers, especially between the years 1890 and 1911,³ the rôle of the pancreas in digestion remained an unsettled question until the studies of Pavlov.⁴ Pavlov worked with dogs, in which animals he produced the fistulae which bear his name. By means of a fistula he was able to obtain pure pancreatic secretion, in which he demonstrated the presence of proteolytic, amylolytic and lipolytic enzymes. In later years Pratt⁵ and still later McClure and Pratt³ convincingly confirmed Bernard's observations that excluding pancreatic secretion from the intestines of dogs was immediately followed by lack of absorption of gross amounts of ingested foodstuffs.

In 1902 Bayliss and Starling⁶ published their observations on the factors concerned in stimulation of external pancreatic secretion. From these observations they postulated the attractive theory that there exists a substance in the intestinal mucosa, designated as prosecretin, which is converted into another substance designated as secretin by action of hydrochloric acid coming from the stomach. They further postulated that the secretin thus formed was absorbed and carried through the blood stream to the pancreas, and after reaching that organ excited its external secretion. The studies of the many observers who have confirmed the experimental observations of Bayliss and Starling have been correlated and are critically presented in a publication of Fairall and Ivy.⁷ Fairall and Ivy working with dogs also studied the effects on the enzymic concentrations of the secretions of a pancreatic transplant of administering different types of foodstuffs. From the results of these studies, together with those derived

* Received for publication April 13, 1937.

[†] Gastroenterologist to Fifth Medical Service and to Out-Patient Department of Boston City Hospital, Assistant Professor of Gastroenterology, Boston University School of Medicine, Boston, Mass.

from the critical review of the work of Bayliss and Starling and subsequent experimentors, Fairrell and Ivy⁷ in 1926 confirmed the conclusion previously expressed by the present author⁸, which was that all the studies mentioned established the highly important physiological facts that (1) stimulation of the external secretion of the pancreas is of humoral origin, although the exact mechanism remains unsettled, (2) ingestion of food is followed by the secretion of pancreatic juice, and (3) the external secretion of the pancreas plays an essential rôle in digestion. Since this publication in 1926 Ivy⁹ has succeeded in making a preparation from dogs' duodenal mucosa which he considers contains a hormone possessing the physiological properties ascribed to secretin. This work will be discussed later.

All of the investigations summarized in the foregoing paragraphs have been carried out on lower animals. In how far the results are applicable to man can be determined only by actual observations on human subjects. However, there is pathological evidence confirming the importance of the external pancreatic secretion in man, for example, disease which excludes pancreatic juice from the intestines of man is known to be accompanied by marked disturbances in the digestion and absorption of food. Various investigators have studied pancreatic secretions obtained from operative fistula in man. As the result of such a study Glaessner¹⁰ found that the amount of pancreatic juice secreted was greatly augmented by food. Wohlgemuth¹¹ obtained pure pancreatic juice from a traumatic fistula in a human subject. Other than for the presence of the fistula, the subject's physical state was apparently normal. These studies showed that the ingestion of food consisting largely of fat brought about pancreatic secretion showing the greatest degrees of all types of enzyme action while the secretion following a carbohydrate meal showed the least. On the other hand, carbohydrate meals were followed by the secretion of the largest volumes of pancreatic juice, while fatty foods produced the least. Mocquot, Joltrain and Laudat¹² also found that carbohydrate food produced the greatest amount of pancreatic juice, but that a meat meal was followed by the least. Thus the results of these observations showed the existence of a relation between the kinds of foodstuffs ingested and the amounts of pancreatic juice secreted, and also the concentration of enzymes found in this juice. Kahn and Klein¹³ also found that "There was a different rate for the secretion of the various enzymes and therefore a different rate for the discharge of the total amounts at one time, with corresponding variation in the frequency of renewal of the supply of enzymes of the gland." Wohlgemuth¹¹ and Mocquot, Joltrain and Laudat¹² observed intermittent secretion of pancreatic juice through the fistula, while von Friedrich¹⁴ observed continuous secretion by his patient. Neither these observers nor Poljak¹⁵ were able to demonstrate a relationship between the type of foodstuffs fed and the degree of concentration of the enzyme specific for that kind of food.

The studies on pancreatic secretion of man discussed were all carried out on subjects in more or less pathologic physical states, while the experi-

mental methods employed are open to criticism. Nevertheless, the findings show that in man, as well as in lower animals (1) Ingestion of food is followed by the secretion of pancreatic juice, and (2) the external secretion of the pancreas plays an important rôle in digestion. These findings are obviously of great importance. Nevertheless, they do not establish the mechanism which stimulates the secretion of pancreatic juice nor the conditions under which intestinal digestion actually occurs in the living normal man. It is generally accepted that the end products of intestinal digestion in man are the same as those in lower animals, that is, carbohydrates are converted into monosaccharides, fats into soap and glycerol, and proteins into amino-acids, and that these end products are absorbed as such. However, it should be noted that it was not until the work of Folin¹⁶ and of Van Slyke¹⁷ that the absorption from the gut of the end products of protein digestion was established. It is only fair to add that all the phases of the various processes involved in the digestion and absorption of both proteins and fats are not yet fully established.

There are available but comparatively few studies on the physical and chemical conditions under which intestinal digestion occurs in man. Practically the only studies on the physical chemistry of intestinal digestion in the living normal human subject are those of McClendon et al.,¹⁸ Hume, Denis, Silverman and Irwin¹⁹ and that of the present author and his co-workers which will be discussed later. In fact many of the conditions affecting enzyme action were not established until the publication of the work of Sorensen²⁰ in 1909. This work permitted the development of reliable methods for indirectly quantitating enzymes present in pancreatic juice, first by McClure²¹ and then later by Willstätter²² and Ivy^{9,23}. These methods, the roentgen-ray, electrometric apparatus, the duodenal tube, together with advances in physical chemistry and biochemistry, permitted the development of procedures and methods for studying digestion in the living man. The most extensive systematic studies of this subject were carried on first by McClure and co-workers²⁴ and later by Christiansen of Copenhagen²⁵. Several studies on man have been made by Chutay²⁶ and less extensive observations by other investigators, these studies will be discussed later. The clinical importance of all these various studies is due primarily to the objective demonstration of phenomena occurring in normal human subjects which will permit comparisons with those occurring under similar experimental conditions in abnormal subjects. The explanations of the mechanisms of functional activities producing the phenomena are of only indirect value in the actual use of the tests in medical diagnosis. This indirect value lies in the fact that usually, but not always, the more nearly correct the physiological basis for a clinical test or procedure the more reliable are the results for diagnostic purposes. Thus, the interpretations of results of investigations made for clinical purposes may be, indeed often are, radically different from those which are of value in the medical sciences.

Long experience in clinical medicine, clinical research and investigations in pure science have led the present author to conclude that the investigator who has not had a considerable experience in the actual practice of medicine rarely is capable of the type of interpretation required for purposes of clinical diagnosis. In relation to human medicine both physiology and pathologic physiology may be, therefore, approached from two viewpoints. The discussion of the physiology and pathologic physiology of the pancreas, which follows, is from the viewpoint of the practitioner of medicine.

In pursuit of clinically applicable studies of the physiology of intestinal digestion in normal man suitability of analytical methods and proper experimental procedures and conditions are of essential importance. Such methods, procedures and conditions were developed by the present author and co-workers and on them depends very largely the reliability of the studies whose discussion follows.

One of the problems was whether or not reliable means could be developed for demonstrating pancreatic stimulation by examination of duodenal contents. The measure of pancreatic activity chosen by the present author was that of enzymic concentration, while Christiansen²⁵ selected the quantity of enzymes secreted. The results obtained by both of us showed that stimulation of the enzymic function of the pancreas could be demonstrated by examination of duodenal contents obtained under suitable experimental conditions and analyzed by proper methods.

THE EFFECTS OF FOODSTUFFS ON CONCENTRATION OF PANCREATIC ENZYMES

The present author's studies²⁷ showed that pancreatic juice containing variable concentrations and amounts of enzymes is obtainable from the normal human duodenum during the fasting state. It was further found that following cessation of stimulation of the pancreas the juice secreted again assumed the characters of that obtained during the fasting state. Stimulation was characterized by a much greater average concentration of the three types of enzymes and by a greater uniformity in the degrees of enzymic concentrations.

Observations were made to determine possible variations in the concentrations of the various enzymes during different periods in which the secretion of pancreatic juice was stimulated by ingested foodstuffs. For this purpose normal subjects were fed pure protein, and duodenal contents were collected over relatively short intervals during the period of pancreatic stimulation. This study showed that in different fractions of duodenal contents collected from the same subject the concentrations of the same type of enzyme remained fairly uniform. Further observations on the uniformity of enzymic concentrations were made on specimens of duodenal contents collected over hourly periods from normal subjects. The meals were of such size that the minimum emptying time of the stomach as determined

by fluoroscopic examination was more than four hours. This permitted the collection of not less than four specimens from each subject. The study showed that each of the several types of enzyme varied moderately in the degrees of its concentration in the different hourly specimens of duodenal contents from the same subject, but that there was no regular manner in which the variations occurred, that is, there was no constant systematic increase in the enzymic concentrations throughout the period of pancreatic stimulation.

Studies were made to ascertain whether the greatest degree of concentration of a given enzyme occurred in the presence of a meal composed of a type of foodstuff corresponding to its substratum. For this purpose normal subjects were given at different times a meal composed of various pure proteins, fats or carbohydrates. The results showed conclusively that no one kind of pure foodstuff stimulates the greatest concentration of its specific type of enzyme. Christiansen²⁷ made similar findings in relation to the amounts of enzymes secreted under comparable experimental conditions. In addition to the studies discussed, a series of normal subjects was subjected to intraduodenal administration of pure foodstuffs²⁸. The latter were cottonseed oil, special preparations of casein and of beef furnished by the Arlington Chemical Company and dextrose. The oil was mixed with water and the other substances dissolved in water and then introduced into the duodenum through the duodenal tube. Foodstuffs thus administered produced in the same subject enzymic concentrations of duodenal contents entirely comparable to those obtained after their oral administration. After intraduodenal administrations the bile and gastric fractions of the collected duodenal contents were analyzed as well as the pancreatic fraction. The findings apparently eliminated the possibility of the volume of one fraction masking the effects of the other fractions through dilution, because the increases or decreases in the analytical figures rarely failed to coincide.

The foregoing studies show (a) There is a period following the ingestion of foodstuffs during which definitely increased concentrations of pancreatic enzymes are demonstrable in the pancreatic juice collected from the duodenum of man, this period is the result of stimulation of the activity of the external function of the pancreas. During this period of stimulation the concentration of each type of enzyme varies much less than in duodenal contents collected either before or after stimulation. Christiansen found an increase in the amounts of enzymes secreted during this period.

(b) In duodenal specimens collected over succeeding periods during which pancreatic stimulation is in process the enzymic concentrations remain fairly uniform in degree.

(c) The greatest degree of concentration of a given enzyme is not governed by the type of foodstuff corresponding to the specific substratum in which the enzyme acts. However, the degrees of concentration of all

types of pancreatic enzymes are related to the kind of foodstuff fed, oil giving the greatest degree and carbohydrates the least. Christiansen also found well defined relationships between the amounts of enzymes secreted and the type of foodstuff administered.

In relation to clinical diagnosis these findings are important not because of the physiological implications, which will be discussed later, but because they furnish norms with which the findings obtained from pathological subjects can be compared.

EFFECTS OF INORGANIC SUBSTANCES ON CONCENTRATION OF PANCREATIC ENZYMES

Having established the rôle played by foodstuffs on the external secretory activity of the pancreas it was considered of equal importance to study the effects of representative inorganic substances. The substances chosen were distilled water, chemically pure hydrochloric acid, phosphoric acid, sodium phosphate and magnesium sulphate.

Comparative studies^{7, 8, 28, 29} of the degrees of enzymic concentration were made in duodenal contents derived from the fasting duodenum, after the ingestion of tap water and after drinking weak cornstarch solution. For this purpose the fasting duodenal contents were collected over periods of 30 minutes from normal subjects, then 50 c c of tap water were given and the contents collected for two hours, in fractions of one hour each. The enzymic concentrations of the two fractions were comparable. The results representative of those obtained from this comparative study are outlined in the following table. To the table are added the figures representing the enzymic concentration of duodenal contents collected after the ingestion of a mixture of olive oil and tap water. The experiments with the oil feedings and those with the fasting duodenum and tap water feedings were made on separate days.

TABLE I

Enzymic Concentrations of Duodenal Contents Collected from the Fasting Duodenum and after the Ingestion of Tap Water, or of Cornstarch Solution or of Olive Oil

Enzymic Concentration			Food Ingested
Proteolytic in mg N P N	Lipolytic in c c N/10 NaOH	Amylolytic in mg glucose	
1.8	0.5	0.3	Fasting duodenum
5.7	3.5	2.6	25 c c of olive oil and 25 c c tap water
2.7	0.0	0.0	50 c c 0.5% cornstarch
1.5	0.1	0.0	50 c c tap water

In the above table comparison of enzymic concentrations of the contents of the fasting duodenum with those found after drinking water shows that after the ingestion of water or weak cornstarch solution the degrees of con-

centration of the various enzymes present in the duodenal contents are comparable with those present in the fasting contents. However, after the ingestion of olive oil, the degrees of action of all these various enzymes were increased in the duodenal contents of each subject.

Comparative studies were made of enzymic concentrations of duodenal contents obtained after the ingestion of olive oil and of various hydrochloric acid mixtures. The determinations were made in duodenal contents from normal subjects. Results representative of those obtained in a series of experiments are outlined in the following table.

TABLE II

Enzymic Concentrations of Duodenal Contents Obtained after the Ingestion of Hydrochloric Acid and Olive Oil

Enzymic Concentrations			Food Ingested
Proteolytic in mg N P N	Lipolytic in c c N/11 NaOH	Amylolytic in mg glucose	
4.3	1.2	1.2	100 c c N/10 HCl and gum arabic
2.2	0.0	0.2	60 c c N/10 HCl and gum arabic
2.7	0.7	1.4	50 c c N/10 HCl solution
5.7	2.5	2.5	25 c c each of olive oil and water

Study of the table shows that the greatest enzymic concentrations were obtained in duodenal contents derived after the ingestion of olive oil, and that acid was a much less potent stimulant. The latter acted comparably to water. This is to be anticipated because ingestion of water stimulates the production of acid gastric secretion. Observations in which phosphoric acid was used instead of HCl gave results comparable to those described for the latter acid.

Studies²⁸ were made on five normal subjects of the comparative stimulative effects of foodstuffs, HCl and $MgSO_4$ solutions in the secretions of pancreatic juice. These subjects were given, in aqueous suspension, 100 c c of 50 c c pure cottonseed oil, or a solution of one of the following substances, 50 grams of fat-free beef peptone, 50 grams pure dextrose, 8 grams of $MgSO_4$ crystals or N/40 HCl. Results representative of those obtained are outlined in the following table.

The findings of this study, represented in table 3, show that magnesium sulphate is a more potent stimulant to the secretion of pancreatic enzymes than is HCl solution or dextrose. They also clearly show that inorganic substances, including HCl, are less potent stimulants to the secretion of pancreatic enzymes than are fats or protein foodstuffs.

The studies which have been briefly described show that the inorganic substances, hydrochloric acid, phosphoric acid and water, are weak and inconstant stimulants to the flow of pancreatic enzymes. Magnesium sul-

phate was a more constant and potent stimulant than were these other substances, although it fails to stimulate in about 20 per cent of normal subjects. At the best, magnesium sulphate was a much less reliable and less powerful stimulant than either fat or protein foodstuffs.

The action of these inorganic substances on the exocrine pancreatic function is comparable to that described by Ivy⁹ after parenteral administration of a substance designated purified secretin. In relation to clinical medicine the studies on inorganic substances are important because they show that such compounds are not satisfactory stimulants when the pancreatic fraction of duodenal contents is examined for diagnostic purposes.

ALKALI SECRETORY ACTIVITY OF PANCREAS

The studies which have been discussed showed that different types of stimulants reacted differently on the external enzymic functions of the pancreas. Obviously, these findings explain the logic of studying the effects of various types of stimulants on the alkali secretory activity of the pancreas. For this purpose pH and buffer values of duodenal contents were determined.³⁰ All pH determinations were made electrometrically. The buffer values were determined by titrating duodenal contents either with tenth normal hydrochloric acid or with sodium hydroxide solution, according as to whether the original material was alkaline or acid. This was accomplished by bringing a definite quantity of the duodenal contents to the neutral point by the addition of standard acid or alkali, the pH values being determined initially and the neutral point evaluated by further potentiometric comparisons, after addition of successive portions of titration solutions. Studies were first made on duodenal contents collected from normal subjects in the fasting state, and then after ingestion of tap water. The pH values obtained during fasting were 6.0 to 8.1 and after water drinking were 7.6

to 8.3, which indicates that water drinking caused some stimulation of alkali secretion. After these preliminary studies the subjects were fed pure foodstuffs or mixtures of them. Duodenal contents were collected during the period of stimulation of the pancreatic juice and pH determined. It was found that duodenal contents derived after the ingestion of olive oil or of arrowroot starch were alkaline (pH above 7), the pH varied from 7.2 to 8.1. On the other hand, duodenal contents collected after ingestion of the protein, edestin, or the mixture of foodstuffs containing edestin were acid (pH below 7), the pH varied from 3.2 to 6.7. The correctness of these findings has been verified by others^{18, 19, 21, 22, 23}. The buffer values of the duodenal contents obtained after administration of foodstuffs were surprisingly uniform. Such uniformity indicates that the physical chemical factors governing the buffer conditions were approximately the same in all specimens of duodenal contents, i.e., the findings indicate that the various types of food substances had about the same stimulating effect on the production of buffer substances. Obviously, this finding indicates that foodstuffs stimulate the alkali secretory activity of the pancreas in a manner differing from their stimulation of the enzymic activities.

The determinations of the pH values discussed above do not afford data concerning the rapidity with which gastric chyme is neutralized within the duodenum. In order to obtain such data⁸ duodenal contents for pH determinations were obtained by aspiration from the first portion of the duodenum, the metal tip was either just beyond the distal end of the sphincter, or within the sphincter. Collections were made over periods of a few seconds to several minutes, depending on the time necessary to collect a quantity sufficient for potentiometric purposes, about 5 c.c. A second duodenal tube was placed in the stomach in order to prove that the ingested meal gave rise to an active flow of acid gastric juice, the acidity being determined by titration and electrometrically. The substances fed were olive oil and N/10 HCl. These studies showed that the acidity of gastric chyme is neutralized the instant it reaches the duodenum and that the neutralization occurred in the region of the pyloric sphincter. The neutralization may be compared to that produced by pouring an acid solution onto the surface of an alkaline fluid with diffusion downward.

Independent stimulation of the two types of pancreatic secretions, alkali and enzymic, was studied further. For this purpose enzymic concentrations of duodenal contents were determined after the ingestion of olive oil and various mixtures of hydrochloric acid. The results of these studies showed that only an indifferent relationship existed between the enzymic secretory function of the pancreas and the alkali secretory function. The independence of these two secretory activities is also maintained by other observers^{23, 24, 25}. The studies on the alkali secretory function of the pancreas furnish normal findings with which those on abnormal subjects may be compared.

MECHANISM OF PANCREATIC STIMULATION

The foregoing findings which have been discussed furnish data not only applicable to clinical studies but also relating to the factors concerned in stimulation of the external secretory functions of the pancreas. Such stimulation is usually attributed by physiologists to the hypothetical hormone designated secretin. Bayliss and Starling⁶ proposed this theory on the basis of two observations. First, they found that when acid is applied to a denervated loop of the upper jejunum the pancreas secretes. Second, they also found that acid extracts of the duodenal and jejunal mucosa contained a substance called by them, "secretin," which excites the pancreas to secrete when injected intravenously. However, substances possessing the action of "secretin" have been found in many animal tissues other than duodenal and jejunal mucosa and its extraction with hydrochloric acid might very well form various compounds (due to decomposition of proteins, etc.) whose parenteral administration would stimulate the secretion of pancreatic juice. A concise critique of the animal experimentation relating to hormonal stimulation of the pancreas is reported by Farrell and Ivy⁷, together with the observation that they were able to stimulate the secretion of pancreatic juice by a denervated autotransplant of the pancreas in the dog. Their conclusion confirms the opinion of the author that the work of Bayliss and Starling indicates humoral stimulation but not necessarily hormonal stimulation. In more recent studies Ivy⁸ produces stimulation of the flow of pancreatic juice in dogs and in man by the parenteral administration of a preparation designated as a purified secretin. These findings apparently establish a humoral stimulation of the exocrine functions of the pancreas in both lower animals and in man.

The establishment of the chemical (humoral) stimulation of the exocrine functions of the pancreas is of sufficient importance to justify the large amount of experimentation carried on by various observers during the past 32 years. However, merely because a parenterally administered substance stimulates pancreatic secretions does not prove the existence of a hormonal (secretin) mechanism of such stimulation. Realizing this, Ivy made further investigations⁹ in which he found that his purified secretin and also various foodstuffs failed to influence the enzymic concentrations of pancreatic juice of dogs. Obviously, these findings favor the correctness of the hormonal (secretin) stimulation in dogs. However, although Ivy's purified secretin⁹ did not affect the concentrations of pancreatic enzymes in man, the investigations of the present author and others have unquestionably established that such concentrations are definitely affected by various foodstuffs. These reported differences suggest that there possibly exist differences in the mechanisms of pancreatic stimulation in dog and man. It would be logical to postulate that the carnivora require only a restricted type of pancreatic stimulation since protein is the predominant foodstuff, while omnivora might require more complicated mechanism because of the various

elements habitually entering into their diet. Another important fact is that the experimental observations have always been made on animals whose physiological states have been drastically modified. These considerations make it seem hazardous to conclude from experimental data now available that the mechanisms of stimulation of the exocrine functions of the pancreas in man are necessarily similar or indeed comparable to those in lower animals.

There are various studies made by the author and Christiansen the results of which are not compatible with the secretin theory of stimulation of the pancreas. It will be recalled that the secretin theory postulated an acid state of duodenal contents. However, studies discussed above show that the duodenum during digestion is either alkaline or the amount of free HCl is not more than a trace. Certainly hydrochloric acid could not have played a role in the stimulation of the pancreas in the author's patient with achylia gastrica, the gastric contents were kept alkaline by mixing sodium hydroxide with the foodstuffs fed. These findings negative the application of the secretin theory, as usually described, to man. Measuring the production of enzymes in terms of enzymic concentrations shows such production to be governed by the type of stimulant administered. Were pancreatic stimulation in man the result of only the one substance, secretin, the consistent variations which have been found for different types of stimulants would not be anticipated.

Both Ivy⁹ and Chiray¹⁰ found that the parenteral administration of substances designated by them as purified secretin stimulated an increase in the amount of pancreatic juice secreted by normal men. Chiray also found an increase in the concentration of enzymes, while Ivy did not. The difference in findings is logically explained as due to differences in the substances administered. These findings are evidence favoring the correctness of the conclusions drawn independently by the present author and by Christiansen, which is that the alkali and enzymic activities of the pancreas are independent functions. The author's studies⁶ of this problem were made on normal young men. The subjects were fed water, hydrochloric acid, olive oil mixed with hydrochloric acid, and olive oil mixed with water. Two tubes were used simultaneously, the tip of one entering the duodenum and the tip of the other remaining in the stomach. The latter tube permitted it to be shown that the contents of the stomach were actively acid throughout the experimental observation periods. Throughout these periods gastric acidity was titrated and electrometric pH determinations were made of the gastric and duodenal contents together with estimations of the concentrations of the pancreatic enzymes. These findings showed that water and hydrochloric acid solutions stimulated the secretion of alkali by the pancreas but produced no demonstrable effect on the concentration of enzymes. On the other hand, the olive oil meals stimulated both the alkali and enzymic fractions of pancreatic juice, the gastric contents being actively acid. These

findings indicate that the two exocrine pancreatic functions react differently Christiansen ²⁵ investigated the subject with unique experimental procedures From his studies he concluded that the secretion of alkali and the secretion of enzymes represent independent functions

PATHOLOGIC PHYSIOLOGY OF EXTERNAL PANCREATIC FUNCTION

The experimental findings and their relation to the mechanisms of external pancreatic functions which have been discussed furnish a basis for the study of abnormal pancreatic conditions, whether functional or organic In making such studies propriety of experimental methods and procedures is of essential importance Those developed and used by the present author will be discussed in connection with the considerable number of other procedures which have been proposed for the purpose of eliciting evidence of pancreatic involvement Critical review of them demonstrates that they are designed to show functional disturbances in the pancreas either directly or indirectly through the secondary effects on metabolism They may be classified as follows

I Test for demonstrating the secondary effects of pancreatic function

A Effect on carbohydrate metabolism

1 Glycosuria

(a) Dynamic

(b) Potential

2 Cammidge pancreatic reaction ³⁷

B Unclassified effect on metabolism

1 Loewi mydriasis test ³⁸

C Effect on alimentation

1 Steatorrhea and percentage of undigested fats ^{3, 39, 40}

2 Azotorrhea and creatorrhea ^{41, 42}

3 Urinary ethereal sulphates

II Direct tests for pancreatic function

A The estimation of the concentration of pancreatic enzymes in vitro (quantitative)

1 Estimation in excreta

(a) Trypsin in feces ^{43, 44 45}

(b) Diastase in feces ^{46, 47 48}

(c) Lipase in urine ⁴⁹

(d) Diastase in urine ⁴⁷

2 Estimation in gastric contents

(a) Trypsin, diastase and lipase after an oil meal ^{50, 51}

3 Estimation of enzymes in duodenal contents

4 Estimation in blood

(a) Diastase ^{47 52 53}

(b) Lipase ^{54 55}

B The estimation of the concentration of pancreatic enzymes in vivo

- 1 Keratin coated capsules containing methylene blue ⁵⁶
- 2 Glutoid capsules of Sahli containing iodoform ⁵⁷
- 3 Nucleus test of Schmidt, ⁵⁸ and the modifications of Einhorn, ⁵⁹ and Kashiwado ⁶⁰

Descriptions of these various tests are found in the encyclopedic work of Weiss ⁶¹ and in other publications ^{79, 11, 12, 62}

Of the above tests but few have proved to be of practical value. Steatorrhea, azotorrhea and creatorrhea occur in the presence of advanced disease of the pancreas. In the presence of complete exclusion of pancreatic juice the nucleus test may still be positive. Of the various examinations of substances in the blood the most efficient ⁶³ is the test for lipase devised by Cherry and Ciandall ⁵⁵. In relation to lipase in the blood, it is of interest to note the work of Boldyreff ⁶⁴. This investigator has concluded from experimental observations that the external pancreatic secretion furnishes enzymes to the blood. Both Boldyreff ⁶⁴ and Oelgoetz ⁶⁵ attribute great importance to this phenomenon. However, neither of these observers has given consideration to the rôle played by the liver in destroying pancreatic enzymes reaching it in the portal blood, which phenomenon is discussed by Fischler ⁶⁶. Examination of the pancreatic moiety of duodenal contents furnishes the most useful information concerning the functional state of the pancreas. The reliability of such examinations depends (*a*) on the correct use of the duodenal tube, (*b*) on procedures which insure the collection of representative specimens of duodenal contents, (*c*) on the use of a stimulant which will uniformly cause secretion of pancreatic juice and (*d*) on analytical methods incorporating the necessary physiochemical principles. The present author has developed a system of duodenal analysis ²¹ which incorporates all these requirements. Sufficiently large numbers of normal and pathological subjects have been studied to establish the status of this system. In brief the method consists of giving the duodenal tube with the subject in the fasting state, and verifying the position of the tip of the tube by fluoroscopy. Cream or oleic acid is used to stimulate pancreatic secretion, and a specimen is then collected which is representative of the duodenal contents during the period of such stimulation. The specimen is analyzed for enzymic activities by the methods devised by the author, these incorporate the necessary physiochemical principles. Willstätter ²² and also Ivy ⁹ have developed reliable analytical physico-chemical methods for estimating enzymic activities. The status of the results obtained from the author's system of duodenal analysis in relation to clinical diagnosis was established by the study of large numbers of patients representing a considerable variety of diseases. Results representative of those obtained in patients suffering from organic pancreatic affections are outlined in the following tables.

TABLE IV

Representative Duodenal Enzymic Concentrations in Pancreatic Disease

Subject	Proteolytic non-protein nitrogen mg	Lipolytic N/10 NaOH c c	Amylolytic glucose mg	Diagnosis
Normal controls	20	10	10	
4*	50	02	04	Acute pancreatitis convalescing
	19	07	19	
3*	11	03	05	Chronic pancreatitis
	08	03	03	
2*	00	02	20	Cancer head of pancreas
1*	25	16	20	Cancer of body and tail of pancreas

* Laparotomy

The effects of pancreatic disease on the enzymic concentrations of duodenal contents, demonstrated by studies comparable to those outlined in table 4 together with those reported by other investigators⁶⁷ may be summarized as follows

Extensive involvement of the pancreatic parenchyma, due to acute pancreatitis or less extensive pathologic lesions accompanying chronic pancreatitis, is associated with a decrease below the minimum normal limits of at least two of the three types of enzymic concentrations in the duodenal contents. It is possible that the diminution in enzymic concentrations in some of these cases is due, in part, to obstruction to the flow of pancreatic secretion by the pathologic process, as well as to actual destruction of pancreatic parenchyma.

Cancer of the head of the pancreas produces a marked decrease in enzymic concentrations, although extensive carcinomatous involvement of the pancreas, not involving the head or the duct of Wirsung, does not demonstrably affect the enzymic concentrations of duodenal contents.

Slight involvement of the pancreatic parenchyma, when due to acute pancreatitis or pancreatic cyst, does not affect the enzymic concentrations of the duodenal contents.

The functional state of the pancreas, as reflected in changes in enzymic concentrations in duodenal contents, was investigated⁶⁸ in patients suffering with diseases of the liver or gall-bladder. In chronic cholecystitis, with or without gall stones, about 50 per cent of the cases showed slight abnormality in pancreatic enzymic function. This was most often expressed as a diminution in the concentration of lipase. The presence or absence of jaundice exerted no demonstrable influence on pancreatic function. Comparable evidence of pancreatic functional disturbance was demonstrated in 95 per cent of the patients who had undergone cholecystectomy. Calculous obstruction of the ampulla of Vater will produce low enzymic concentrations. These findings have been verified

by others^{67, 69} Very abnormal enzymic concentrations were also found in acute cholecystitis. However, normal enzymic concentrations were found in cancer of the bile ducts which did not involve the pancreatic ducts. Mild disturbance of pancreatic function was found in 70 per cent of patients with cirrhosis of the liver and in 50 per cent of patients with toxic jaundice. Only about 16 per cent of patients with uncomplicated duodenal ulcer gave evidence of mild pancreatic dysfunction.

The combined study of the pancreatic and biliary moieties of duodenal contents has been found of value in differentiating between benign and malignant causes for jaundice and in localizing the site of the lesions. The important findings in such differentiation may be outlined as follows.

Normal enzymic concentrations and no bile demonstrate that the lesion is in the biliary tract above the ampulla of Vater. If bile reappears after repeated instillation of magnesium sulphate solution into the duodenum it is highly probable that the obstruction of the biliary tract is of benign character. The more concentrated the bile that is obtained, the more probably benign is the lesion. But if bile does not reappear, the chance that the lesion is benign is much more remote.

Abnormal enzymic concentrations, with the initial presence of bile, especially if the bile is relatively concentrated, or if it reappears after intraduodenal instillation of magnesium sulphate solution, suggest benign obstruction in the region of the ampulla of Vater. In such cases the reappearance of bile may be accompanied by increase in enzymic concentrations.

Abnormal enzymic concentrations, when bile remains absent from the duodenum in spite of repeated intraduodenal administration of magnesium sulphate, suggest cancer of the head of the pancreas.

Duodenal contents grossly discolored with blood, with abnormal enzymic concentrations, and containing no bile denote cancer involving the head of the pancreas, common bile duct and wall of the duodenum.

VITAMIN C AND INFECTION ¹

By JAMES M. FAULKNER, M.D., F.A.C.P., and F. H. L. TAYLOR, Ph.D.,
Boston, Massachusetts

INTRODUCTION

THE conception that scurvy has an important relationship to infection is far from new. In fact, some of the earliest descriptions of scurvy bear witness to this relationship and account for the fact that scurvy was often considered an infectious disease. Echthius, whose comments on scurvy were published in 1585,¹ is referred to by James Lind² as follows: "Echthius seems to be the first who gave rise to the opinion of its being a contagious or infectious *lues*. He was led into that mistake by observing whole monasteries who lived on the same diet, and in the same air, at once affected with it, especially after fevers, which no doubt might become infectious in close and confined apartments. He imagined, therefore, that a scurvy might in a manner be the *crisis* of a fever, which as such he deemed contagious." This relationship was more clearly recognized by Maynwaringe,³ a century later, who wrote: "That Feavers and Scurvy do commute and complicate, daily experience doth manifest to Learned Physicians, that are *critical* observers and those intermitting *Feavers*, called *Agues*, which are looked upon and accounted by the vulgar and unknowing, as trivial slight diseases, and, as I have heard some say, *An Ague in the Spring is as good as Physick* but they little consider what *ruine* these *Agues* bring to the best tempered bodies, what alteration and change they make in the *mass* of blood, seldom recovering its former state and purity, if they continue long and neglected and at their cessation and departure you think all is done, the danger and the *prejudice* past, and you *in statu quo prius*, but now begins the *Scurvy* to act its part, slyly and gradually to creep upon you, except by the advice of a skillful Physician, you raze out the *vestigia* of the former disease, *characterized* and *impressed* upon the *Viscera* for nutrition, by *alienating* their ferments from their genuine and *primitive* natures, from which *seminaries* the *Scurvy* will spout forth.

"Hereby you may perceive the succession and commutation of diseases, how one disease *introduceth* and is the *procludium* to another."

However faulty may have been the reasoning of the early commentators as to the fundamental cause of scurvy their observations on the effect of

The authors are indebted to Merck & Co. and to Hoffmann, La Roche & Co. for ascorbic acid used in this investigation.

infections in precipitating the disease have been repeatedly confirmed. Time after time epidemics of scurvy have been seen to sweep through an inadequately fed populace on the heels of a contagious disease. As recently as 1917 this phenomenon was reported from the prison camps of the Central Powers.⁴

Of late years, improvement in the dietary of the poorer classes has been sufficient to make scurvy a relatively uncommon condition confined largely to infants, solitary living bachelors, alcoholics, and patients on certain rigid diets, such as for peptic ulcer. Even in individual cases, however, the influence of infection in unmasking a latent scurvy is often manifest. As Hess⁵ has remarked, "Infection is the most important condition which may suddenly and precipitously induce scurvy."

The chemical isolation of vitamin C or ascorbic acid and the subsequent development of methods for its quantitation in plant and animal tissues have made it possible to study its metabolism in health and disease in a more exact way than hitherto. Vitamin C is a powerful reducing agent and its ability to reduce 2,6-dichlorophenol-indophenol under suitably controlled conditions has been shown to be highly specific.^{6,7} With this dye vitamin C can be titrated directly in the urine or in the protein-free filtrate of blood serum or plasma.

It has been observed that in normal individuals the blood serum level of ascorbic acid is between 0.7 and 2.5 mg per 100 c.c., and even within this normal range differences can ordinarily be accounted for by differences in dietary intake of vitamin C.⁸ Elimination of vitamin C from the diet has been observed to be followed by a gradual fall in the blood level of the vitamin until it reached a value as low as 0.2 mg per 100 c.c.⁹

The urinary excretion of vitamin C is in the normal healthy subject dependent upon the dietary intake.^{9,10,11} Although observations on the serum level or urinary output of vitamin C in infection have been few and contradictory,¹²⁻²¹ experimental evidence has been accumulating that there is an increased demand for the vitamin in infection. Rinehart²⁰ has shown that this is the case in active rheumatoid arthritis and rheumatic fever, and Heinemann²¹ has confirmed this in other infectious diseases. However, studies of the vitamin C metabolism in a large series of cases with infection are lacking. The purpose of the observations reported here was to seek evidence in regard to the effect of infection on the vitamin C metabolism by estimating the blood ascorbic acid in a large group of hospital patients and controls, and by "balance" experiments in a few patients with infections.

METHODS

The reduced ascorbic acid in the blood serum was determined by the method of Taylor et al.²² Repeated estimations have shown an accuracy of 0.2 mg per 100 ml of blood serum. The data presented were collected from 165 individuals representing a cross section of the hospital population.

including, as controls, members of the staff and technicians, as well as patients without infections

These individuals have been arbitrarily divided into four groups. Group I consists of individuals free from infection who had been on a diet containing some fresh fruit or green vegetables. Group II consists of patients with infections who had been on a diet containing some fresh fruit or green vegetables. Group III consists of patients free from infection who had been on diets lacking in fresh fruits and green vegetables. Group IV consists of patients with infections who had been on diets lacking in fresh fruits and green vegetables.

The first group ("adequate" vitamin C intake without infection) was composed of 43 individuals from all walks of life, the majority of whom were ward patients in the hospital. The average serum level of ascorbic acid in this group was 1.31 mg per 100 c.c. with a range from 0.51 to 2.42 mg per 100 c.c.

The second group ("adequate" vitamin C intake with infection) consists of 66 patients suffering from various infections such as lobar and bronchopneumonia, acute upper respiratory infection, tonsillitis, rheumatic fever, acute gonorrheal arthritis, pyelitis, cystitis, pulmonary and pleural tuberculosis, bronchitis, lung abscess, malaria, acute catarrhal jaundice, staphylococcus abscesses, typhoid fever, streptococcus septicemia, and osteomyelitis. No patient was included who did not exhibit either fever or leukocytosis. The average level of serum ascorbic acid in this group was 0.64 mg with a range from 0.10 to 1.19 mg per 100 c.c. This is about one-half the average value found in the normal group. No correlation between the severity or etiology of the infection and the level of ascorbic acid in the blood was noted except that all of the cases of uncomplicated pyelitis or cystitis, five in number, had normal values. In 10 cases of active rheumatic fever included in Group II the average value was 0.48 mg per 100 c.c. with a range from 0.10 to 0.85 mg per 100 c.c., essentially the same as for the group as a whole.

The third group ("inadequate" vitamin C intake without infection) consists of 27 patients. In these the average serum ascorbic acid value was 0.48 mg with a range from 0.11 to 1.26 mg per 100 c.c.

The fourth group ("inadequate" vitamin C intake with infection) consists of 29 patients. In these the average value was 0.47 mg of ascorbic acid per 100 c.c. with a range of from 0.21 to 0.91 mg per 100 c.c., essentially the same as for Group III. (Figure 1)

Clinical signs of scurvy such as spongy, bleeding gums or spontaneous hemorrhages into the tissues were not observed in either Group I or Group II but were noted in ten patients in Group III and three patients in Group IV. There was no significant difference in the serum level of ascorbic acid between the patients with scurvy and those with equally poor diets without scurvy.

On encountering these results the question arises, "Could they not be due to lessened intake of vitamin C from lack of appetite or defective absorption associated with infectious disease?" In answer to this, it may be said that many of these patients were observed to be partaking of an adequate diet in the hospital, and in many the determination of serum ascorbic acid was done within a day or two of the onset of the disease before it would be expected that the effects of faulty absorption would become manifest

A study of the vitamin C balance was carried out in four individuals with chronic infections—two patients with pulmonary tuberculosis, one with rheumatic fever, and one with lung abscess. Inasmuch as the observations in all four yielded essentially the same results only one case will be described in detail. T W was an elderly man with advanced pulmonary tuberculosis, who weighed 50 kilograms. Previous to entry to the hospital he had been

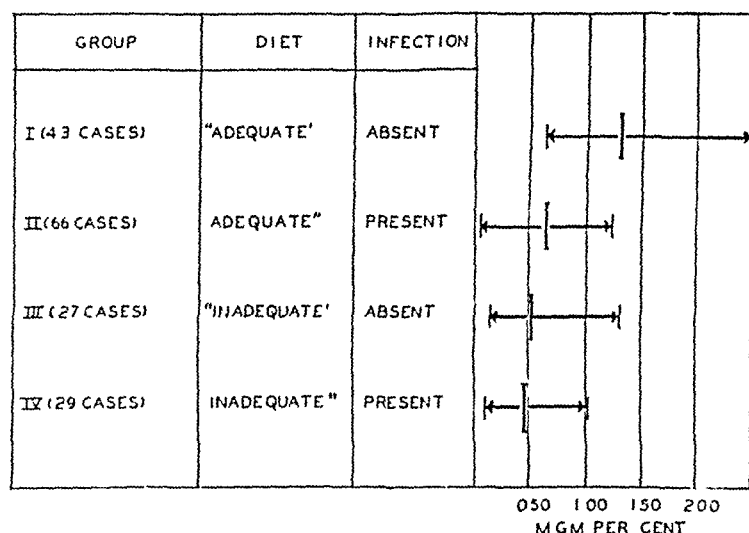

FIG 1 Average serum ascorbic acid and range of values in various conditions

on a diet containing raw fruit or cabbage several times a week. His clinical condition remained essentially unchanged throughout the course of the observations. During his stay in the hospital he was kept on a basal diet which contained no fresh fruit, tomato or cabbage, in other words, it was moderately low but not completely lacking in vitamin C. On admission the serum ascorbic acid was 0.30 mg per 100 cc while the average total daily excretion into the urine was 3 mg, a very low value. These figures showed no essential change over a control period of three weeks. During the succeeding 10 days he was given on separate occasions one intravenous dose and two oral doses of one gram each of ascorbic acid. These large single doses of ascorbic acid were followed during the first 24 hours by an increased excretion of the vitamin in the urine amounting to 254 mg after the intravenous injection, and 21 and 71 mg, respectively, after the oral administrations. During the second 24 hours on each occasion the urinary

excretion fell to its previous low values. At the end of this period the plasma ascorbic acid had risen to 0.95 mg per 100 c.c. He was then given 500 mg of ascorbic acid by mouth daily for four weeks. The response to this amount was shown by a prompt rise in the plasma ascorbic acid to 1.31 mg per 100 c.c., accompanied by a marked increase in the urinary excretion to from 200 to 300 mg per day. Ascorbic acid administration was then discontinued for four weeks and there was a rapid fall in the plasma ascorbic acid to its preexisting low level. At this point increasing doses of ascorbic acid were given by mouth beginning with 100 mg per day for 13 days, then 200 mg per day for 17 days and finally 300 mg per day. It was not until the latter dosage had been instituted for several days that the serum ascorbic acid level and the urinary excretion of the vitamin rose to normal values (figure 2).

FIG. 2. The effect of oral administration of ascorbic acid on the serum values and urinary excretion of this substance in a patient with pulmonary tuberculosis.

DISCUSSION

The above experiment indicates that this patient who had active tuberculosis required more than 200 mg of ascorbic acid per day to keep his plasma level and urinary secretion of the vitamin at normal levels. This may be compared to the figures of van Eckelen²³ and of Heinemann²⁴ who found that the daily requirements of a normal adult weighing 70 kg are about 60 mg.

SUMMARY

The serum ascorbic acid has been estimated in a group of normal individuals, in patients with vitamin C deficiency, and in patients with infectious diseases

The serum ascorbic acid levels in patients with infections are usually well below the values seen in normal individuals and often reach figures encountered in manifest clinical scurvy

The amount of vitamin C in the diet necessary to bring the serum level and the urinary output to normal values in the presence of infection is far greater than the normal requirements

The effect of rheumatic fever on the vitamin C metabolism appears to be the same as that of other infectious diseases

THE EFFECTS OF LARGE DOSES OF BENZEDRINE SULPHATE ON THE ALBINO RAT FUNCTIONAL AND TISSUE CHANGES

By WILLIAM E. EHRLICH, M.D., and E. B. KRUMBHAR, M.D., Ph.D.,
F.A.C.P., *Philadelphia, Pennsylvania*

Of the synthetic preparations of the epinephrine group, benzedrine (phenylisopropylamine) is in some respects more efficient than epinephrine and ephedrine, and also has additional therapeutic effects. As a sympathetic stimulant it produces mydriasis and piloerection (Alles¹, Prinzmetal and Bloomberg², Myerson, Loman and Dameshek³). It raises both blood and spinal fluid pressure, the rise being maintained for a longer period than after injection of the other two drugs (Alles¹, Piness, Miller and Alles⁴, Haitung and Munch⁵, Tainter⁶, Myerson, Loman and Dameshek³). Like these drugs, it increases the number of erythrocytes and leukocytes in the blood, and to a lesser extent the hemoglobin and the corpuscular volume (Myerson, Loman and Dameshek³). Applied to the mucous membranes of the nose, Eustachian tube or middle ear, benzedrine has a marked decongesting effect (Bertolet⁶, Bryne⁶, Scarano⁶, Wood⁶). In addition, it has been found to diminish the sense of fatigue, to prevent sleep, and to be of therapeutic value in the narcolepsies and allied conditions (Prinzmetal and Bloomberg²). Finally, it has been shown to lessen or abolish spastic manifestations of the gastrointestinal tract within a few minutes (Myerson and Ritvo⁷).

Most of these studies have been on clinical material, those on animals were not continued over long periods and did not include postmortem studies which might throw light on possible toxic effects.

It seemed desirable, therefore, to undertake studies on rats which would disclose signs of toxicity when benzedrine in hypertherapeutic amounts was given over long periods, and also establish the postmortem changes following lethal doses.

METHODS

For these experiments, 171 albino rats, weighing from 50 to 385 grams, were used, 145 rats were injected subcutaneously with benzedrine sulphate which had been dissolved in saline solution and sterilized by heat. The amount of benzedrine given by single injections varied from 1 to 500 mg per kilo of rat weight. Injections, with but few exceptions, were made on

* Presented in brief before the Section on General Medicine of the College of Physicians of Philadelphia, January 25, 1937, and the American Association of Pathologists and Bacteriologists, Chicago, March 25, 1937. Received for publication April 13, 1937.

From the Department of Pathology, University of Pennsylvania.

Aided by a grant from Smith, Kline & French, Inc.

the first, fourth and sixth days and thereafter daily—six days a week—in one group for one and one-half weeks, in another for three weeks, in another for six weeks. Surviving rats were sacrificed and immediately autopsied 24 hours after the last injection, except in the case of one lot that was used to study the effect of increasing doses.

Of the remaining 26 rats, which served as controls, nine were injected with 0.5 to 2.0 c.c. of saline, while 17 received no injections.

To estimate functional changes, we observed the general behavior of the rats, the weight curve, the blood picture, and the blood urea. The blood picture was determined from a drop of blood from an incision in the dorsal surface of the tail. To avoid a possible anemia from loss of blood, we made only two to four counts on each rat of the number of the red and white cells and differential counts, according to standard routine. The blood urea was determined from blood collected after the animals had been decapitated. For these determinations we are indebted to Dr. W. G. Karr, of this University, who used the method of Folin and Wu.

For the morphological study, pieces of liver, kidneys, adrenals, heart, aorta, intestine, spleen, lungs and brain were fixed in alcohol, formalin and Zenker-formalin. The sections were stained with hematoxylin-eosin, Azur II-eosin, Best's carmine and Sudan III. In most instances stains for calcium and iron were also made.

RESULTS

1 *Lethal Dose* The lethal dose was determined first, since it should also show toxic effects, if there were any, especially with high sublethal doses. The results of these studies are given in table 1. Since heavier (older) rats

TABLE I
Lethal Dose of Benzedrine in Different Weight Groups

Dosage mg./1000 grams	Weight 50 to 95 grams				Weight 100 to 195 grams				Weight 210 to 385 grams			
	No. of rats	Average weight (grams)	Number dead after first injection	Number dead after fifth injection	No. of rats	Average weight (grams)	Number dead after first injection	Number dead after fifth injection	No. of rats	Average weight (grams)	Number dead after first injection	Number dead after fifth injection
20	3	88	0	0	13	140	0	1†(8)

Figures in parentheses = percentage dead

* In this rat death was due to paratyphoid

† In these rats the cause of death could not be ascertained, because they were found to be eaten up or completely autolyzed

‡ In one of these rats death was due to pneumonia, whereas the other apparently died from benzedrine

regularly died from much smaller doses per kilo than lighter (younger) ones, the results are presented in three groups: the first comprising animals weighing 50 to 95 grams, the second, 100 to 195 grams, and the third, 210 to 385 grams.

If we consider as the minimum lethal dose one which kills half or more of the animals injected, we find that for rats weighing 50 to 95 grams, this dose is about 200 mg per kilo, for rats weighing 100 to 195 grams, 50 to 60 per kilo, and for rats weighing 210 to 385 grams, 30 to 40 per kilo. Of the 10 rats which died with smaller doses, six could be examined histologically. Of these, one showed a heavy paratyphoid infection, and one an extensive purulent pneumonia, whereas the other four apparently died from benzedrine.

In general, the rats died the more quickly the larger the dose given. This holds true for all three weight groups.

The question why seven rats (excluding those that had complicating infections) died only after several injections cannot be answered with certainty. But since four of them received the second injection three days after the first only, and the third two days after the second, and since these rats died only after they had received two to three *daily* injections, it might very well be that the drug was not eliminated completely during the 24 hours between the injections, or that they had not recovered completely before they were again injected. As far as we can learn, there is as yet no knowledge of the method and rate of elimination of the drug or of its destruction within the body. That its action lasted more than eight hours can be deduced from the fact that treated rats ate less the next night (12 to 24 hours after the injection) and that rats which received large doses frequently were found to be still excited 24 hours after the injection.

As to tolerance, we have definite evidence that it was increased by repeated injections, in animals which survived the first four or five. If we injected 20 to 150 mg per kilo for four to 21 days and increased doses thereafter until the animals died, we found (table 2) that in most animals the dose had to be increased to 300 to 500 mg per kilo to have a lethal effect.

In regard to the minimum lethal dose, our figures are considerably higher than the 25 mg per kilo reported by Hartung and Munch⁵ for benzedrine hydrochloride. While there should be little difference in the action of equal doses of the two salts, 100 mg of the hydrochloride being equivalent to 107 mg of the sulphate, the discrepancy may be explained by the different weights (ages) of the animals used. In our series only the third group consisted of adult or almost adult rats, while those of Hartung and Munch may all have been fully adult or even aged.

2 General Behavior. As soon as 15 minutes after the first injection the rats began to run around excessively, to gnaw at the iron wires of their cages, and, when a dish of water was in the cage, to splash in it. The pupils were very wide and with larger doses did not react to light. The degree

and the course of this excitement varied with the dose of benzedrine. Rats receiving 1 to 5 mg per kilo of weight were not at all or moderately excited after two to three hours, almost calm after four hours, and quite calm after six to seven hours, rats receiving 5 to 20 mg were much excited after two and a half hours, moderately excited after four hours, and calm to moderately excited after six to seven hours, rats receiving 20 to 80 mg were very much excited after two and a half to three hours and after four hours, and moderately to much excited after six to seven hours. Rats which received 30 mg or more showed very queer movements, they ran backwards or in circles, even had difficulty in walking, often sat up on their hind legs, pawing the air and falling over backward. Many rats developed diarrhea.

TABLE II
Lethal Dose of Benzedrine if Applied Daily in Increasing Doses (27 Rats)

No of rat	Weight (grams)	Benzedrine mg /1000 grams	Total mg per kilo given	Total no of doses	Found dead hrs after last injection

Figures in parentheses = number of injections given at each dosage level

After repeated injections similar observations were made. After the third or fourth injection, it was also noted that the rats which received 30 mg or more fought a great deal. In two rats receiving 10 and 30 mg per day a very unusual phenomenon was observed. Three hours after the second injection they were found to gnaw their own thoracic skin.

After injections had been continued for more than one to two weeks, rats did not react as strongly as they did after the first injections. They were less excited, and for shorter periods.

A rat about to die from benzedrine lay down and "faded away." Al-

though the death of practically all the rats was observed, nothing approaching tremors or convulsions, as reported by Alles¹ for guinea-pigs, was observed at any time

3 Weight Of the 55 rats the weights of which have been followed, 30 were discarded when found to be sick from spontaneous diseases. Of the 25 remaining rats, 16 have been followed for three to six weeks. The weight curves of these rats are given in figures 1 to 3, together with normal weight curves, as given by Donaldson and Ferry⁸. Comparison shows that at first most rats stopped growing for three to four weeks, after which most of those receiving less than 20 mg. per day grew again, while those receiving higher doses failed to do so. It can also be seen that younger rats (figure 1) did better than older ones (figure 2).

FIG 1 Transient inhibition of growth by daily injections of benzedrine ——— Experimental rats (male, weight group 50 to 95 grams), the dotted continuation gives the curve of the one rat that survived ——— Normal weight curve based on data of Donaldson, Dunn and Watson - - - - Normal weight curve based on data of Ferry An arrow indicates when benzedrine dosage was started

FIG 2 Transient inhibition of growth by daily injections of benzedrine ——— experimental rats (male, weight group 150 to 205 gm), ———, - - - -, and arrow, as in figure 1

FIG 3 Transient inhibition of growth by daily injections of benzedrine ——— experimental rats (female, weight groups 50 to 95 and 100 to 130 gm), ———, ———, and arrow, as in figure 1

Weight changes and food intake of the remaining nine rats (four treated with benzedrine, and five controls) are given in table 3. They correspond to the previous figures. In addition, they show that the daily food intake, as measured by weighing the amount of food (Purina Dog Chow) given in the morning and left on the next morning, was conspicuously lowered in

TABLE III
Changes of Weight and Food Intake During Nine Days of Treatment

No of rats	Original weight (grams)	Treatment	Average weight increase (per cent)	Average daily food intake (grams)
<i>Control Group</i>				
2	75-100	None	+51	} 17.5
2	80-100	1 c c saline	+58	
1	155	1 c c saline	+16	
<i>Benzedrine</i>				
2	85-100	50-100 mg	+16	} 13.7
2	155-165	25 mg	+ 3	

the treated animals as compared with the controls. This finding indicates that decreased food intake is a factor in the inhibition of growth.

4 *Red and White Blood Cells* The changes in the number of erythrocytes and leukocytes in the blood have been followed in 36 treated and six control rats. In all instances the determinations were made 24 hours after the last injection. As 21 of the treated animals and four of the controls had to be excluded on account of the presence of spontaneous disease at autopsy, the counts on 15 treated and two control rats only were available.

The changes in the number of erythrocytes in our treated rats are presented in figure 4. For comparison, the normal increase in the number of erythrocytes (which in our rats amounted to 0.22 millions of erythrocytes per 10 grams of weight increase) has been given. We found that, with the exception of two rats which received 1 mg benzedrine daily, all our rats responded with an erythrocytosis. Whereas in the rats receiving 2 to 5 mg of benzedrine daily this increase amounted to 40 per cent on the sixteenth day, in those receiving 20 mg, it amounted to about 50 per cent after 16 to 23 days, and in those receiving 40 to 80 mg to 55 per cent, after 43 days, i.e., on the last day of this experiment.

The individual leukocyte counts were not as uniform as the erythrocyte counts, and there were no distinct differences in the animals treated with different doses. On the average, at first both granulocytes and lymphocytes

Fig. 4. The percentage changes in the number of erythrocytes after 2 to 5, 20, and 40 to 80 mg of benzedrine daily. An arrow shows when benzedrine dosage was started.

rose considerably. After 16 days there was a marked preponderance of granulocytes, and after 23 days of lymphocytes. After 30 days, however, both granulocytes and lymphocytes had returned to normal in spite of the daily dosage being continued (figure 5).

These findings correspond in general to those of Myerson, Loman and Dameshek in men, as well as to those which have been obtained with epinephrine and ephedrine in a variety of animals. As to the mechanism producing these changes no new information was obtained. It may be mentioned that in a few animals tested the icterus index was normal.

5. Blood Urea. The blood urea has been determined in 33 treated and five control rats, 28 to 29 hours after the last injection. In all the rats receiving 1 to 20 mg of benzedrine daily for three or six weeks, or 30 to 200 mg for one and a half weeks (with the exception of three rats which had

an extensive spontaneous disease) the blood urea was found to be within normal limits 17 to 26 mg per cent (average 23 mg per cent), as compared with 20 to 24 mg per cent (average 23 mg per cent) in our controls. In the four rats which received 40 to 80 mg daily for three or six weeks it was found to amount to 34, 50, 52 and $70 \pm$ mg per cent. Since two of these rats showed no spontaneous disease whatsoever, and another had one tapeworm only, it may be assumed that in these animals the rise in blood urea was due to the injections.

FIG 5 The percentage changes in the number of granulocytes and lymphocytes after 1 to 80 mg of benzedrine daily. An arrow indicates when benzedrine dosage was begun.

6 Gross Pathology In the animals which were killed by the benzedrine, various lesions were found. Frequent changes were marked and sharply delimited constrictions of the small intestine, air and fluid in stomach and intestine, congestion of the liver, either contraction or congestion of the spleen, and subpleural hemorrhages in the lungs. As the changes in the amount of blood in spleen and liver appear to be of special interest, we have tried to analyze them (table 4). Correlating these changes with the time which elapsed between injection and death, we find that the congestion of the liver was most marked in the animals which died after two hours,

TABLE IV

Amount of Blood in Liver and Spleen in Rats Which Died from Benzedrine, as Compared with the Time the Rats Survived

Died hrs after last injection	No of rats	Average dose of benzedrine (mg.)	Average weight (grams)	No. of rats showing different amounts of blood in					
				Liver			Spleen		
				Normal	Slight incr	Great incr	Decr	Normal	Incr
—	10	0	112.5	10	0	0	1	9	0
1-1	4	300	124	1	2	1	2	0	2
1-2	7	179	121	0	0	7	4	2	1
3-5	13	167	130	0	7	6	6	1	6
6-24	3	57	155	1	1	1	1	1	1

less marked after three to five hours, and less marked still after six to 24 hours, whereas the changes in the spleen showed no relationship to the time of death after injection. However, comparison with the dosage of benzedrine (table 5) shows that most of the animals which received 30 to 100 mg. had congested spleens, and those which received 150 to 400 mg. contracted spleens, whereas the livers showed no relationship. From these findings we may conclude that the contraction of the spleen was due to the action

TABLE V

Amount of Blood in Liver and Spleen (Percentage Incidence) in Rats Which Died from Benzedrine, as Compared with the Dose Given

Dose of benzedrine (mg.)	No. of rats	Average weight (grams)	Died hrs after last injection (average)	Amount of Blood in					
				Spleen			Liver		
				Decr	Normal	Incr	Normal	Slight incr	Great incr
0	10	112.5	—	10*	90	0	100	0	0
30-100	12	147.5	4.4-5.6	25	17	58	8	42	50
150-400	15	115	2.5	67	13	20	7	27	66

* Percentage of rats

of benzedrine, whereas the congestion of the liver and spleen was merely a sign of the circulatory insufficiency that existed just before death. The fact that the spleens of the rats which received smaller doses of benzedrine were congested in most cases may be explained by the assumption that in these animals the effect of circulatory failure was greater than that of the benzedrine, whereas in the animals with larger doses the effect of the drug

predominated. As the surviving animals which were killed 24 hours after the last injection showed no lesions attributable to the treatment, they are omitted here.

7 Histology A Necroses With the exception of 11 rats which were eaten up or in an advanced state of autolysis, all rats were carefully examined histologically. In no instance, not even in animals which for six weeks received 40 to 80 mg. of benzedrine daily, were we able to find areas of degeneration, necroses or calcification in the myocardium, in the arteries or in the muscular coat of the intestine, as described in chronic adrienalism (Petri⁹). Nor did we find any "parenchymatous degeneration" of the kidneys as described by Chen¹⁰ after administration of ephedrine. Many slides, to be sure, showed vacuolization of the tubular epithelial cells when fixed in alcohol and stained with hematoxylin-eosin, or a fibrinoid granulation of these cells when fixed in Zenker-formalin and stained with Azur II. Although this observation is of interest pathologically and, as far as we know, has not been previously reported, it is not relevant to the present study, as it was obviously dependent upon spontaneous diseases of the rats, especially upon paratyphoid and purulent infections (see table 6).

TABLE VI

Tubular Degeneration of Kidneys as Compared with Benzedrine Injections and Spontaneous Disease

	No of animals	Tubular degeneration			
		0	+	++	+++
Controls (healthy)	15	9	2	3	1
Benzedrine (healthy)					
1-25 mg	13	11	1	0	1
30-50 gm	15	13	1	1	0
60-100 mg	11	11	0	0	0
150-400 mg	13	13	0	0	0
Paratyphoid

Medium	9	0	2	6	1
Heavy	10	0	1	2	7
Purulent bronchopneumonia, appendicitis, middle ear infection, etc	7	3	1	2	1

The only changes which could be connected with the benzedrine injections were necroses in liver, spleen and kidneys, and changes in the sugar and fat depots. Necroses in liver, spleen and kidneys were found only in rats which died from benzedrine. Rats which survived the injections never showed any necroses or scars when killed later. If we compare the occurrence of necroses with the dosage of benzedrine (table 7), we find that only those rats which died from 30 to 100 mg. of benzedrine per kilo exhibited necroses, whereas those which received higher doses did not. A similar

TABLE VII
Liver Necroses as Compared with the Dose of Benzedrine Given (Single Doses)

Dose of benzedrine (mg)	No. of rats	Liver necroses			
		None	Slight	Medium	Extensive
30-40	9	1	1	2	5
50-60	11	2	3	4	2

		None	Slight	Medium	Extensive
40-80	2	0	0	1	1
100-150	7	1	3	2	1
200-400	18	18	0	0	0

B. Carbohydrate and Fat Changes Changes in the sugar and fat deposits on the other hand were found in both groups of rats. If rats, after one and a half weeks of treatment, were killed by ether one day after the last injection, and if they had no spontaneous diseases, the glycogen content of the liver as well as of the para-aortal, para-renal, para-adrenal and mesenteric fat tissue, as seen by Best's carmine stain, was found to be increased in those rats receiving more than 25 mg, whereas the fat content of these organs was found in Sudan III stained slides to be decreased (table 9). Similar results were obtained by a chemical analysis for which we are indebted to Dr. Evans of the Cox Institute (table 10). Since fat tissue could not be obtained in an amount large enough to permit such an analysis, this was not studied. Instead, the heart glycogen was determined, this, however, appeared to be within the normal limits (table 10).

In the rats killed after three or six weeks of treatment the glycogen could not be determined correctly, because the time between decapitation and fixation of tissues was long enough to have permitted loss of glycogen. The fat, however, could be estimated, since its values do not change as quickly after death as those of glycogen. The results of this estimation are in accord with the findings after one and one-half weeks (table 11).

TABLE IX

10-20	5	1	3	1	0	0	0	2	3
40-80	3	3	0	0	0	0	0	3	0

In addition, they seem to indicate, that after three or six weeks' treatment the decrease in fat is more pronounced still, and that it is apparent already in animals which received less than 25 mg of benzedrine per day.

In the rats dying after one or two injections of benzedrine, no glycogen was found in liver or fat tissue, if the animals died after six to 11 increasing doses, however, invariably an increase in glycogen was noted. The fat content of the liver was not changed in the first group, whereas in the latter group we found no fat whatsoever in the liver and a markedly decreased amount in the fat tissue.

Concerning the significance of these findings, it may be mentioned that after epinephrine the liver glycogen is also first decreased and then increased (Cori¹¹). As to the mechanism involved in these changes we have no new suggestions to offer.

COMMENT

The question whether benzedrine if given in large doses has toxic effects or not is difficult to answer. We have found that in experimental doses (which it should be remembered are from five to several hundred times the human therapeutic dose) it may cause excitement, diarrhea, mydriasis, transient inhibition of weight increase in young rats, erythrocytosis, leukocytosis and changes in the glycogen-fat content of liver and fat tissue. Most of these changes were temporary, some for hours only (excitement, mydriasis, diarrhea), some for weeks (erythrocytosis, leukocytosis, inhibition of weight increase). The changes in the glycogen-fat content of liver and fat tissue appeared to be permanent during the time that benzedrine was given.

It was also found that the lethal dose was proportionately higher for small (young) rats than for large (old) ones, and that large doses caused more marked and longer lasting changes in both large and small rats than did small ones. For instance, most of the animals receiving 25 mg of benzedrine or more were much more affected than those receiving smaller doses, they were the only ones which showed, (1) queer body movements

after each injection, (2) a definite increase in glycogen and a definite decrease in fat in liver and fat tissue, (3) a persisting failure to increase in weight, and (4) a persisting increase in the number of erythrocytes in the blood

Whether or not these changes should be looked upon as toxic, appears to be a matter of definition, for if we should call those doses toxic which merely produce transient, undesirable functional variations, then such relatively small doses as 2 to 5 mg of benzedrine per kilo would be regarded as toxic. But if we regard as toxic only those doses which produce actual lesions, i.e., pathologic tissue changes, then the toxic dose appears to be practically the same as the lethal dose. This in rats under 100 gm weight was found to be about 200 mg per kilo, in rats of 100 to 195 gm, 50 to 60 mg, and in rats over 200 gm, 30 to 35 mg.

The evidence is clear cut that smaller (younger) rats are more resistant to equivalent doses of benzedrine than larger ones. The reason for this, however, is quite obscure to us, especially as we know of no studies that demonstrate the fate of benzedrine in the body. Whether the younger animal can break down or excrete the substance more rapidly or completely than the older, or whether the younger tissues are intrinsically more resistant to the drug, or the circulation more efficient in the young, are questions that remain unanswered.

SUMMARY

The functional and structural changes produced by the subcutaneous injection of benzedrine sulphate into rats were studied in widely varying doses over varying periods. One hundred and seventy-one albino rats, weighing from 50 to 385 gm, were used. One hundred and forty-five were injected subcutaneously with doses of 1 to 500 mg per kilo from 1½ to 6 weeks.

The minimum lethal dose decreased with the weight (age) of the rats. In animals of 50 to 95 gm it amounted to 200 mg, in rats of 100 to 195 gm, to 50 to 60 mg, in rats of 210 to 385 gm, to 30 to 35 mg per kilo. After repeated injections an increased tolerance was noted.

If 2 to 5 mg or more were given, the rats showed excitement, diarrhea, mydriasis, transient inhibition of weight increase, erythrocytosis, leukocytosis and so on. With 25 mg and more they showed an increase in glycogen and a decrease in fat in liver and fat tissue.

In rats which died from the drug, frequent changes were. Constrictions of the small intestines, congestion of the liver, either marked constriction or congestion of the spleen and subpleural hemorrhages in the lungs. Rats which died from 30 to 100 mg of benzedrine showed necroses in liver, spleen and kidneys, whereas those which died from higher doses did not. Lesions in the myocardium, arterial or intestinal walls, such as observed in chronic adrenalism, were not found. Rats killed after recovery from non-lethal doses showed no detectable lesions.

CONCLUSIONS

The minimum lethal dose of benzedrine sulphate given subcutaneously to rats is from a hundred to a thousand times per kilo the usual therapeutic dose given man orally

The greatest non-toxic dose, i.e., that which fails to produce transient variations, appears to be from 2 to 5 mg per kilo, in other words about 10 to 50 times per kilo the usual human therapeutic dose

The failure of repeated sublethal doses to produce detectable lesions in rats indicates that there should be a considerable margin of safety in the proper therapeutic use of the drug

CASE REPORTS

GLOSSOPHARYNGEAL NEURALGIA DUE TO AN IMPACTED WISDOM TOOTH *

By DAVID RIESMAN, M D , Sc D , F A C P , *Philadelphia, Pennsylvania*

IN a recent article Hoover and Poppen¹ call renewed attention to tic douloureux involving the glossopharyngeal nerve. They report two cases of their own and collect a number of others recorded in the literature. The pain is of the same nature as that of tic douloureux except that it is located at the base of the tongue and in the back of the throat instead of in the face.

Medical treatment is not very effective—it consists chiefly of the inhalations of from 15 to 30 drops of trichlorethylene three or four times a day. Such treatment frequently stops the pain but does not in any sense bring about a cure. In a number of cases, including one of Hoover and Poppen's surgical treatment has been employed. In their opinion intracranial section of the ninth nerve in the posterior fossa, a formidable operation, is the procedure of choice.

I want to call attention to a cause of glossopharyngeal neuralgia which should it exist renders such an operation entirely unnecessary, nothing more being required than the extraction of an impacted wisdom tooth.

The first case concerns a man about 50 years of age who began to have violent pains in the throat on eating and speaking. He was obliged to lecture frequently and sometimes while lecturing he would be seized with such a spasm of pain that he thought he would become delirious. The pain would not last long but while it lasted the patient had to hold on to something for fear of falling in a faint. The pain was felt in the back of the throat, in the tonsillar region, and at the base of the tongue—never in the teeth. Throat specialists told him he had gout and ordered salicylates and iodides, but the treatment had not the slightest effect. A dentist declared the teeth normal except for an impacted wisdom tooth. Thinking that this tooth might be responsible for the frightful neuralgia, I insisted that the tooth be removed. It was extracted with difficulty by the late Dr. Matthew Crver, but from that time on the man has been entirely free from pain. The tooth itself was healthy.

The second patient was a man of 48 years who while in good health was suddenly seized with agonizing pain in the throat which unlike the pain in the first case was not paroxysmal but was more or less constant. For 10 days he had hardly had any sleep despite a variety of strong sedatives. A dentist had declared his teeth to be normal. The case was so similar to the other that I suspected an impacted wisdom tooth. The roentgen-ray films showed such a tooth. It was extracted and the pain disappeared immediately and never returned. Neither of the two patients had any toothache or connected the pain with his teeth.

On the basis of these two impressive experiences I would advise search for an impacted wisdom tooth in cases of glossopharyngeal neuralgia and if one is

* Received for publication JANUARY 22, 1937

found, that it be extracted, regardless of a dentist's opinion to the contrary, before resorting to more radical measures

MAJOR PSYCHOSIS IN UNDULANT FEVER *

By FRED E. ANGLE, M.D., and W. H. ALGIE, M.D., *Kansas City, Kansas*

MENTAL symptoms have frequently been observed during the course of undulant fever. In a study of 154 cases, we have encountered only one major psychosis. We found no reference to this condition as a complication of undulant fever in the American literature. Nouvilas¹ reported four cases from the Asylum of Navarre, Roger² collected 15 cases from the literature and reported three of his own. In a series of 200 cases, Cantaloube³ reported delirium in 12 and mental confusion in ten.

CASE REPORT

T. H., a white male business college student, aged 23, was admitted to the hospital January 8, 1936, in a state of violent catatonic excitement.

His illness had begun December 20, 1935, with a sore throat, chilly sensations, fever of 102° F, sweating, stiffness and soreness in the back of the neck. Two weeks later, as he continued to have fever from 100° F to 101° F and drenching sweats, he was sent to a hospital where it was found that his blood serum agglutinated *Br. abortus* in a dilution of 1:640. It was learned that he had been a habitual drinker of raw milk. His condition was diagnosed as undulant fever. After a short period of observation he was sent home. January 6, he was despondent, irritable, and, at times, mildly delirious. On this date he was given 0.25 cc of *Br. abortus* vaccine intramuscularly. This was followed in a few hours by increased fever, chills, and a more severe delirium. The reaction subsided promptly but recurred the next day following the administration of 0.5 cc of the vaccine. He was mildly confused when seen in consultation January 8. It was decided that he should be sent to the hospital for observation. When the ambulance came for him, he became very excited, negativistic and violent.

The family history was entirely negative for mental disturbance.

He had never had a severe illness. He was intelligent and had never shown any psychopathic tendency.

Examination. He was six feet one inch tall and weighed 190 pounds. His axillary temperature was 103° F and his pulse rate was 120 per minute. Detailed physical examination was impossible on admission because of his violent activity but after large doses of sedatives, he became quiet enough to permit completion of the examination which revealed nothing but a moderate pharyngitis and a dry swollen tongue.

Laboratory examination. Hemoglobin 84 per cent (Sahli), red blood cells 5,700,000, white blood cells 8,150 with 63 per cent neutrophils, 34 per cent lymphocytes, and 3 per cent eosinophiles. The serum agglutinated *Br. abortus* in a dilution

* Received for publication January 25, 1937

of 1 1280 Blood Wassermann and Kahn tests were negative Urine Specific gravity 1 009, albumin, negative, sugar, negative, microscopic examination, no cells or casts

He was very ill, during the first week his pulse ranged from 120 to 150 per minute and his rectal temperature from 104° to 105 8° F He perspired so profusely that he became dehydrated in spite of an increased oral intake and parenteral administration of fluids The latter part of the first week he developed a productive cough with râles in the right hilus region and base These signs disappeared in a few days While the fever was at its height a mild intention tremor of the hands was present The temperature reached its peak January 14, after which it fell gradually and by the end of the second week it was only 99 6° to 100° F There were no abnormal physical findings at this time No specific therapy was attempted after admission to the hospital

A lumbar puncture was made January 11, with the following findings Clear fluid, 18 cm of water pressure, no block, cell count 1, no increase in globulin, Wassermann negative and no decolorization of gold solutions Blood cultured the same day was negative a week later The intradermal test with *B abortus* vaccine applied the first week was strongly positive At the end of the second week the agglutination titer was still 1 1280

During the first two weeks, his mental state varied from catatonic excitement to stupor He had to be restrained constantly In the excited periods, he was violently hyperactive and very noisy He had both visual and auditory hallucinations to which he responded with obscene accusations and violent threats There were also absurd transient delusions, usually of a grandiose character Disorientation was complete for time and space and partial for persons At times he was rigid, negativistic, and mute He ate very little but took fluids well He urinated and defecated in bed Sedatives had little effect and he slept fitfully, less than five hours in each twenty-four

After the second week, he was less agitated, seldom rigid or mute but was unchanged otherwise The insomnia persisted Early in the fourth week his temperature again increased to 104° F and was accompanied by increased agitation but the temperature subsided to normal in a few days and the agitation decreased From this time there was little evidence of toxemia He ate well and slept fairly well He had lost more than 40 pounds during his illness Repeated neurological examinations revealed no evidence of any focal lesion of the brain or spinal cord Gradually, he became quieter and more tractable and was released from restraints During the latter part of March, he was allowed to be up in his room when supervised and allowed to go to the bathroom He continued to be hyperactive and hallucinated He was very destructive to his clothing and bedding and was frequently nude

April 9, he was transferred to the State Hospital for the Insane at Osawatomie There, he was given a therapeutic course of malaria as an empirical procedure From the early part of May, his mental condition cleared up rapidly and he was dismissed June 15, apparently normal

Since his return he has been seen frequently There has been no psychotic tendency He has regained his normal weight and strength For a time he continued his studies in the business college and reported normal progress At present he is working in a packing plant So far there has been no indication of a return of his undulant fever September 21, 1936, his agglutination titer was 1 10 complete, 1 40 partial and the opsono-phagocytic reaction marked

Note T H was contacted May 1, and found to be employed doing stenographic work There has been no return of his mental symptoms

Comment Although the early symptoms of psychosis had preceded the administration of the vaccine they developed much more rapidly following its

use The symptoms of general intoxication, likewise, were greatly intensified We were so impressed by this fact that we considered it unwise to continue the vaccine therapy The presence of a psychosis, we believed, should be added to the list of contra-indications to the use of vaccine already reported ⁴

The mental symptoms which occur as a result of a toxic or infectious state may develop into typical psychiatric patterns ⁵ Such a case was reported by Nouvilas ¹ in which the admission diagnosis was schizophrenia, but before the patient left the hospital the diagnosis was revised to acute infectious psychosis Our case has many features of catatonic schizophrenia, but due to the rapid evolution with complete recovery and the absence of any previous abnormal mental trends, we believe the condition was an acute psychosis due to intoxication from undulant fever The persistence of the psychosis after the physical signs of intoxication had disappeared is, of course, not unusual in toxic psychosis

According to Roger ² the appearance of psychic disturbances in undulant fever has an unfavorable prognostic significance, 10 of the cases which he collected from the literature died

PROTAMINE INSULIN AS A CONTRIBUTING FACTOR IN THE DEATH OF A DIABETIC PATIENT WITH CEREBRAL ARTERIOSCLEROSIS

By JANVIER W LINDSAY, M D, F A C P, E CLARENCE RICE, M D, F A C P,
MAURICE A SELINGER, M D, and K HAMMOND MISH, M D,
Washington, D C

PROTAMINE insulin was first used in the United States during 1935 by Root,¹ Joslin² and then associates and since then its use has been extended to diabetic patients in other parts of the country under the direction of physicians with considerable experience in the treatment of diabetes mellitus The number under treatment at present in the United States is probably about 3,000 persons

By means of its use it has been possible to convert the severe diabetes of a number of patients not easily controlled by the simpler or regular insulin to a relatively mild form due to the prolonged action of the new insulin which often eliminates the sudden and wide excursions of the blood sugar, replacing these with a flatter type of curve Various other advantages accruing to the patient

* Received for publication January 16, 1937

From the Garfield Memorial Hospital, Washington, D C

from its uses, such as the reduction in the daily number of injections, the elimination of insulin reactions or the lessening of their severity when hypoglycemia was present, have been observed as compared with the results obtained and effects noted, from the previous use of regular or simpler insulin

Joslin² cautioned against the possible dangers from hypoglycemia, especially if two doses of protamine insulin were used. We have used protamine insulin † since January 1936, in the treatment of over 30 patients and at all times have kept in mind its possible dangers. It is because of a fatality occurring during the treatment of one of our diabetic patients with protamine insulin and because of the possibility that the initial coma, which ended in death, was due to prolonged and extreme hypoglycemia resulting from the long action and cumulative effect of the new insulin, that we present the following case report

CASE REPORT

The patient, an unmarried white female, a clerk, developed diabetes mellitus at the age of 44, during the latter part of 1931. Since the onset she had lost 71 pounds (32.3 kg) when first seen in the diabetic clinic on August 26, 1933, had been treated by dietary restriction alone. Subsequent to this a sister developed diabetes following the removal of a goiter and died in coma, and a brother was found by other physicians to have a glycosuria.

At the time of her initial treatment by us she gave no evidence of arteriosclerosis and the only findings of note were evident anemia and a fibroid uterus. Blood pressure averaged 120 systolic and 80 diastolic. The Wassermann and Kahn tests were negative. Following a three week period of unsuccessful dietary treatment she was given standard insulin in increasing doses. On a diet of carbohydrate 90 gm, protein 54 gm and fat 78 gm, she required 4 doses of insulin averaging 18-12-15-7 units daily. Occasional insulin reactions were experienced. Following a period of hospitalization her diabetes was better controlled on carbohydrate 80 gm, protein 43 gm, and 72 gm of fat with insulin in doses of 16-8-12-11 units per day. In May 1934, her basal metabolic rate was minus 5 per cent. Her electrocardiogram showed complexes of low amplitude, with T_{1-2} nearly isoelectric. Her weight had increased from 134 pounds (60.9 kg) to 172 (78.2 kg). In August 1934, because of the hours of her employment her insulin dosage was 22-14-0-12. From this time until April 1936 her diabetes was never satisfactorily controlled, post-prandial blood sugars varying between 244 and 400 mg. In October 1934, she became comatose at night during an insulin reaction, the incident being preceded by a severe diarrhea.

On April 1, 1936, on a diet of carbohydrate 110 gm, protein 50 gm, and fat 61 gm, she excreted 64 gm of dextrose during the 24 hours. Protamine insulin was started on April 4, 1936, with immediate improvement in the control of the patient's diabetes. Subsequent treatment with the new insulin changed the diabetes from severe to relatively mild on the basis of ease of control. A synopsis of treatment is given in table 1.

Throughout the treatment of the patient considerable difficulty was experienced by the staff of the diabetic clinic in maintaining proper contact. Due to her reduced financial status she rarely felt able to take sick leave to attend the clinic oftener than every two weeks. Although she was able to come to the hospital laboratory for blood examinations on Sundays and after work, those attending her were rarely able to meet her at these times. Instructions were often given by letter. During the latter part of August 1936, when notes from the patient stated that she was having insulin

reactions, a number of attempts to communicate by telephone were made without success

On the afternoon of September 3, 1936, a neighbor noticed that the bottled milk delivered to the patient's home that morning had not been removed from the front porch. Upon investigation the patient was found partially dressed and lying unconscious across her bed. One of us (K H M) was called to see the patient and at 5 30 p m found her comatose, with rapid pulse and flaccid extremities. There was no evidence of food having been eaten at any time during the day. Whether or not the morning dose of 30 units of protamine insulin had been taken following the injection of 10 units the night before is not known. One resident in the house reported talking to the patient about 10 00 p m on the previous day, at which time she seemed to be quite normal. Other residents of the home stated that they heard her moving about her quarters between 6 and 7 a m, but no one saw her on September 3, until discovered by the neighbor. The circumstances and findings were believed to be sufficient to warrant a tentative diagnosis of coma due to hypoglycemia. Ten cubic centimeters of 50 per cent dextrose solution were given intravenously without

demonstrable effect at 5 45 p m She was removed to the hospital and admitted there at 6 45 p m

The following additional history was obtained from relatives after admission to the hospital For three weeks prior to September 3, the patient had lived alone in her apartment, her mother who lived with her being out of the city on a visit Her mother stated that several days before she vacated the apartment the patient came home from office in a daze having no recollection of how she reached there after leaving the street car which brought her from work

Examination revealed the findings as noted above, the skin was cool, the tongue was blue, pulse was rapid and thready, breathing labored Rectal temperature was 100° F Blood sugar, 75 minutes after the intravenous injection, was 307 mg Immediately after this 500 c c of 20 per cent dextrose in normal salt solution were given intravenously At 8 30 p m the blood sugar was 500 She seemed to react favorably for a short time during the intravenous injection but returned to the comatose state The circulation improved, the pulse slowing to 100, blood pressure rising to 140 systolic and 85 diastolic Pupils were equal in size and moderately contracted, reacting to light A lateral nystagmus was observed The lower jaw moved with a chewing movement There appeared to be some paresis of the muscles of the right side of the face and saliva drooled from the mouth The extremities were flaccid and knee jerks absent The Babinski and Kernig tests and ankle clonus were absent There was some slight reaction to deep pressure over the bladder

The bladder was catheterized and 60 c c of urine obtained Except for the presence of a large amount of sugar it was normal chemically and microscopically Spinal fluid withdrawn at 9 00 p m was normal, except for the total amount of sugar 165 mg Pressure was normal The electrocardiogram showed no change from one done two years previously At 9 30 p m a generalized convulsion lasting one minute followed by a few minutes of spasticity, was observed A second convulsion occurred at 10 00 p m At 11 00 p m, blood chemical tests gave the following results non-protein nitrogen 34 mg per cent, sugar 380 mg per cent, carbon dioxide combining power 51 volumes per cent

At 1 00 a m, September 4, a convulsion lasting one minute occurred Following this, 200 c c of 20 per cent dextrose in normal salt solution were given The results of further treatment and laboratory examinations are summarized in table 2

Neurological examination at 3 15 p m, September 4, by Dr Philip Litvin showed "the patient to be in coma There was a slight lateral nystagmus, more marked to the right The pupils alternately contracted and dilated, remaining in a somewhat contracted condition There appeared to be some weakness of the right side of the face, but this was not definite A flaccid paralysis of the upper and lower extremities was observed with a slightly positive Babinski test on the right, that on the left being markedly so Impression Cerebral infarct, probably as a result of old diabetes "

The patient's condition remained about the same on the fifth and sixth Neurological examination on the latter date by Dr D D V Stuart, Jr, gave the following result "Slightly contracted pupils, regular and symmetrical, which respond to light Cervical sympathetic response intact Slow lateral oscillatory movement of the eye balls (not a nystagmus) Corneal reflexes absent The ocular fundi were not well seen, but there appeared to be no abnormalities of the discs or the vessels The deep reflexes were absent The right pectoral reflex was present and a slight movement of both feet was noted on stroking the plantar surfaces A slight odor of acetone was noted on the breath Impression No clinical evidence of cerebrovascular lesion The condition was believed to be primarily diabetic and an increased amount of insulin suggested if the spinal fluid sugar content was above 75 mg /100 "

Spinal fluid removed September 8 showed 6 mm of mercury pressure with 380 erythrocytes and 2 leukocytes per cubic millimeter That on the tenth was under

reduced pressure with innumerable red blood cells and 10 white blood cells per cubic millimeter. The presence of free blood was believed to be due to trauma and of no clinical significance, the supernatant centrifuged fluid being colorless. The Wassermann reaction was negative.

The patient remained comatose until death occurred on September 11, at 11 30 p m, a total of eight days. During the illness the rectal temperature gradually rose from 100° F to 105 8°, pulse varied between 100 and 140, respirations between 20 and 30, except during the last two days, when they averaged 40 per minute. Blood pressure averaged 130 systolic, 86 diastolic during the greater part of the illness. Sweating was most profuse at all times. Beginning September 6, nourishment was

given by tube feedings with one liter of normal salt solution subcutaneously daily, a daily total fluid of 3,100 c c being given

Necropsy was performed 11 hours after death. The findings are summarized as follows. The lungs showed passive congestion and superficial atelectasis. The heart was of normal size, the musculature being soft, and on microscopic examination giving evidence of myocardial degenerative change. The mitral valve was thickened and the coronary arteries showed moderate atheromatous changes as did the aorta. The liver was the site of fatty degeneration and chronic passive congestion. The pancreas weighed 50 gm and was unusually soft and hyperemic. On microscopic examination there was found an increase in interstitial connective tissue, the acinar tissue being hyperplastic. Granular degeneration was marked and islet tissue was but rarely recognized. The kidneys showed parenchymatous degeneration, moderate

interstitial fibrosis, but little vascular change. The uterus was twice the normal size, due to a nodular fibroid tumor in the fundus, it being retroverted and bound down firmly to the sigmoid. The left tube and ovary were intimately enmeshed in these adhesions. *B. cloacae* was cultured from the heart's blood.

The most striking changes were noted in the brain, which externally exhibited nothing unusual. The superior surface of the pituitary body was flattened suggesting the probability of increased intracranial pressure. On section the left cerebral hemisphere showed occasional scattered punctate hemorrhagic areas within the cortex and very rarely in the deeper structures. Connected with one of the fissures in the occipito-parietal region was found a cystic space approximately 1.5 cm in diameter, the outer portion lined by typical gray matter, the deeper portions eroded, the wall being covered by a fine fibrinous material. This space is believed to be the result of pressure from fluid accumulating within the fissure, possibly blood which was later absorbed. Section of the right hemisphere revealed more numerous punctate hemorrhages and a smaller cystic space than that described above, lying near the medial surface of the occipital lobe. No gross evidence of thrombus within or hemorrhagic infiltration outside the vessels of the internal capsule was noted.

Microscopic examination. "The right occipito-parietal lobe and the right internal capsule are markedly edematous with perivascular accumulations of fluid. The vessels appear to be sclerotic and calcification of their walls is seen. The appearance suggests a moderate increase in glial tissue. The left internal capsule is very edematous and small foci of degeneration are noted. Small extravasations of blood and some pigment is found about the vessels. Rather similar findings are observed in the left pons. Sections through the choroid plexus of the left lateral ventricle show the ependyma to be normal. The plexus is congested and edematous with some tendency to epithelial desquamation. Many arterioles are completely occluded by calcific thrombi (?), while others show no change. The left choroid plexus in the third ventricle shows similar changes there also being calcium deposits bearing no definite relation to the blood vessels. These appear to be true psammoma. The cyst wall is represented by fragmented bodies of degenerated parenchyma presenting no evident surrounding inflammatory reaction. The cavity is lined by debris which contains many large beaded bacillary forms. In many of the adjacent blood vessels these organisms can be seen, some appearing to form thrombi. The pituitary body is markedly edematous, the basophilic elements predominating."

COMMENT

The history obtained from the patient, relatives and friends indicates that she probably experienced the effects of a relatively low blood sugar on a number of occasions during the late afternoon and evening or early morning over a period of two months preceding her death. Although the lowest blood sugar obtained at any time was 100 mg/100 cc, it seems likely that lower levels were reached during some of the above mentioned periods, however, no examinations of the blood were made at any time between 5.30 p.m. and 8.00 a.m. Persons living in the same building with the patient stated that during the early part of her treatment with protamine insulin she frequently ate more than her diet called for, but that later on she closely adhered to it.

In view of the marked cerebral arteriosclerosis and the maintenance of the blood pressure at a level slightly below normal, it would appear that the patient was more than ordinarily susceptible to the effects of a relatively low blood sugar. We believe that the result of lowering the blood sugar level in this patient to a point considerably below normal would have an effect analogous to

that obtained in a diabetic individual with marked coronary artery sclerosis. Many of the physical findings observed after unconsciousness was noted, are frequently seen in coma due to insulin hypoglycemia, viz., tonic and clonic muscle spasm, lateral movements of the eyeballs and positive Babinski.

Attention is called to the similarity of this case report and Bowen and Beck's³ case 2, with necropsy findings in the brain by Teiplan⁴. White⁵ also mentions the case of a child, who died as a result of hypoglycemia and on whom a complete necropsy was performed, with findings quite similar to ours. The presence of cerebral arteriosclerosis represents the most important point of difference between the pathological changes in the brain of our patient and those mentioned above. Due to the narrowing of the vessels, a reduced amount of dextrose was supplied to the brain unless the blood sugar was maintained above the usual normal. We feel that this abnormality may have caused her to react to the effects of hypoglycemia when the amount of sugar in her blood was lowered to a level which would not have brought on marked symptoms of hypoglycemia in a patient not similarly affected.

At the time of admission to the hospital in a comatose state, the blood sugar was 307 mg, however, the next morning after a total of 145 gm of dextrose had been given intravenously, no insulin having been administered for 24 hours the amount in the blood was 285 mg. Although one neurological consultant felt that the patient's unconscious state was due to acidosis and insufficient insulin, we do not believe that ketosis was a significant factor at any time, inasmuch as the carbon dioxide combining power on hospitalization was 51 volumes per cent and neither acetone nor diacetic acid was present in the urine. The lowest carbon dioxide combining power recorded was 30, on the second day of coma. Diacetic acid was found in the urine once during the course of the illness, over 40 specimens being examined.

Although there is insufficient laboratory evidence to prove conclusively that the patient's coma was caused by insulin hypoglycemia, we feel that the available data strongly support the view that such a condition was an important factor in its production. The possible dangers incident to the use of any insulin preparation with prolonged action and cumulative effect are emphasized. Until the actions of such preparations are more definitely known we feel that their use should be restricted to those who can be kept under rather constant supervision and control.

SUMMARY

- 1 In the case reported, the difficulties in the control of the patient's diabetes were greatly reduced following the use of protamine insulin, however, reactions attributed to insulin hypoglycemia were accentuated.

- 2 Unconsciousness, believed to be due to prolonged and possibly severe hypoglycemia resulting from the cumulative effect of protamine insulin was observed.

- 3 Death followed eight days coma. Necropsy revealed cerebral arteriosclerosis and cerebral edema with some degenerative changes in the brain.

- 4 The possible dangers to the patient from the prolonged and cumulative effect of the more complex insulin preparations are noted.

EDITORIAL

DISCREPANCY BETWEEN EXPERIMENTAL AND CLINICAL KNOWLEDGE OF THE ANTERIOR PITUITARY BODY

VAN DYCKE recently has written a book, "The Physiology and Pharmacology of the Pituitary Body," during the course of which he reviewed more than 5,000 articles. The bibliography fills 200 pages and yet contains but few references to clinical articles. What is most amazing is that practically all of these articles were written within the past 15 years. So many articles are being published in this field that it is virtually impossible for any practicing physician to keep informed regarding this rapidly accumulating knowledge. He is forced to rely on reviews, most of which are very good but all of which reflect the reviewer's sympathies and prejudices. Or he may rely on the publications of commercial houses some of which are good but many of which are cursory and misleading.

In general there are two groups of such articles. The first group comprises those published by workers in the fundamental fields of biology, chemistry, physiology, pathology, anatomy, and so on. Most of these represent excellent work, including detailed studies under carefully controlled conditions. However, an unprejudiced observer is impressed with the discrepancies existing even in this exact field. As an example one may mention the single factor of species difference. Results obtained with the use of one laboratory animal may be quite different when repeated in another laboratory with a different species. Differing methods of preparing the injected material, differing diets and environmental conditions for the animals, the use of animals of different sex or age—these and many other factors make the comparison of results very difficult. The result is that we do not know, for example, how many hormones of the anterior lobe of the pituitary can be regarded as accepted. Is there one gonadotropic hormone, or are there five? The one hormone which always has been above suspicion is the growth hormone, yet recently a voice has been raised to question its specificity.

The second group of articles in this field is that dealing with the clinical application of this knowledge. These articles as a group are far inferior to the first group mentioned. Many of them never should have been written and represent work which never should have been done. Extracts of uncertain character are injected into patients suffering from uncertain conditions and the misinterpreted results are published by indiscriminating editors. The result is extremely confusing to the clinician, particularly if he is being asked to see many patients supposedly suffering from "pituitary disease."

There are two major difficulties in attempting to evaluate the clinical application of our knowledge in this field. The first already has been touched

on, namely, the unsettled condition of our knowledge of the fundamental principles involved. It seems unwise to utilize clinically a hormone which is not understood biologically. Thyroid extract and insulin are used with good results because of the completion of fundamental studies before their use in the treatment of human beings was attempted. On the other hand, the thyiotropic and carbohydrate influencing principles of the pituitary are most interesting but much work remains for the laboratory before these substances should invade the treatment room. Van Dycke records more than 100 "hormones" now on the market which are obtained from the pituitary gland, sex glands, placenta, blood, or urine of animals or man. At the present writing no hormone from the feces is being marketed. Many of these 100 "hormones" are totally unsuited for injection into man.

The second difficulty is that we know so little about the clinical conditions which may arise from a disturbance of the pituitary. We know of acromegaly, dwarfism, Cushing's syndrome, and a few other well defined conditions. The difficulty is that these comprise such a small portion of the cases in which treatment is with pituitary hormones. The literature contains many references to the treatment of "hypopituitarism" and "hyperpituitarism." Such terms are so indefinite as to be meaningless.

Clinicians react to this situation in various ways. Some are busy utilizing "hormones" indiscriminately and are reporting their confusing results. Others have developed an inferiority complex because, in spite of genuine effort, they cannot obtain the dramatic cures which others report. Others are carefully utilizing standardized substances in the treatment of specific conditions and are reporting their negative as well as their positive results. Blessed are they! Others are simply waiting and hoping.

What can be suggested as a way to the solution of this confusion existing between experimental studies and clinical application? The first step might be for all responsible physicians to subscribe to the concluding paragraph in a recent editorial in the *Journal of the American Medical Association*. "These remarks are not intended to reflect upon the importance of the chemical and biological studies of accredited laboratories, the author is filled with admiration for such efforts. Neither do these remarks apply to the carefully controlled clinical application of accepted knowledge by competent observers, this is necessary. Rather are these remarks intended (1) to emphasize the fact recognized by many interested observers that there is a great discrepancy between our laboratory knowledge of the hormones and their clinical application, (2) to suggest that for the present only those clinicians with facilities for critical study be encouraged to inject extracts into patients and that these men be urged to publish their negative as well as their positive results, and (3) to suggest that the large group of physicians not represented in either group mentioned above cease their unstudied injection of unknown substances into unsuspecting patients."

REVIEWS

The Art of Treatment By WILLIAM R. HOUSTON, A.M., M.D., F.A.C.P. 744 pages, 16.5 × 24 cm. The Macmillan Co. New York. 1936. Price, \$5.00

This work is described in the author's preface as a collection of the subject matter presented in a series of conferences with senior medical students and young doctors. The conference style is carried throughout and is always conducive to interest, although, at times, it does not lend itself very well to the subject.

A practical method is introduced for considering therapy in general. Diseases are grouped according to their chief method of treatment: by nursing care, specific psychotherapy or guidance, limitation of life, physiological consideration and experimental treatment. The common cold, typhoid fever and most of the acute specific infectious diseases are included among those diseases treated chiefly by nursing care, lobar pneumonia, in spite of its frequent treatment by specific sera, is also included in this group. It is easy to understand that this method of presentation has many practical advantages, as repetition is largely eliminated and therapeutic methods described in detail for one member of the group may apply with little or no modification to others.

The reviewer does not, however, agree with the author's decision in placing certain pathological conditions in the chosen groups of diseases. Thus, there seems to be no definite reason for including obesity, bronchiectasis and lung abscess among those treated by "limited living", certainly the latter might better be grouped among those diseases treated by nursing care.

The author has evidently drawn on an extensive personal experience and his personality is reflected in his writing. There can be no doubt that he has done a valuable piece of work, especially in his discussion of therapeutic planning. The long introductory section is almost classical in its style, interest, and value.

A criticism that might be offered is that in certain cases discussion is too lengthy and actual advice too brief. For example, in outlining the treatment of exophthalmic goiter no very definite therapeutic plan is presented, the usual time required for iodine remission is not stated, and treatment of thyroid storm and cardiac complications is not mentioned. In the section on diabetes, advice is somewhat indefinite and treatment of complicating infection is hardly mentioned. Diabetic coma is not very well discussed.

The section on psychotherapy contains many very helpful suggestions for the management of the patient, but here, as elsewhere, the author tends to digress from the subject frequently, so that information may be somewhat obscured. The absence of an adequate chapter on physical therapeutic methods is disappointing.

The writing of a textbook on therapy is one of the most difficult tasks an author can undertake but Dr. Houston's contribution should be a valuable addition to our current texts.

T. N. C.

Diseases of the Newborn By ABRAHAM TOW, M.D. 477 pages, 15.5 × 23 cm. Oxford University Press, New York, N. Y. 1937. Price, \$6.50

In the compilation of this work Dr. Tow has been extremely thorough. Practically all of the conditions affecting the newly born have been covered. Even such rarities as the Klippel-Feil syndrome and osteopetrosis receive attention. At times the discussion is extended beyond the neo-natal period, but only in the interests of clarification or completeness. Sufficient stress is laid upon the clinical side of the

book to make it attractive to the practitioner. The literature has been exhaustively investigated and where differences of opinion exist the conflicting views are presented in an unbiased fashion. The author states in the preface "On basis of years of experience on the newborn service at the New York Polyclinic Hospital certain opinions have been formulated and there has been no hesitancy in expressing these opinions when it was felt that they might clarify a controversial subject." Case reports are frequently used to illustrate diagnosis, prognosis or treatment of various diseases or conditions, a method felt by the reviewer to be quite valuable.

An excellent bibliography follows each chapter. The references are well chosen and contain the most modern views on the various subjects.

Adequate use has been made of illustrations, most of which deal with congenital defects, birth injuries, and the apparatus for special pediatric procedures. A number of these pictures are rather blurred as to detail, a factor which makes their value questionable.

The print is of a close small type and the pages are highly glossed, a combination that for prolonged use is rather tiring.

The defects of this volume are more than compensated by its thoroughness and by the excellent presentation. It compares very favorably with other books dealing with this subject and should be of value to both the practitioner and pediatrician.

J E B

Practical Examination of Personality and Behavior Disorders. By K E APPEL and E A STRICKER. 219 pages, 15.5 X 22 cm. The Macmillan Company, New York. 1936. Price, \$2.00.

There are many things in this book which serve to make it both an interesting and useful volume. Although the authors have presented the book ostensibly for medical students and neophytes in psychiatry, they have included material which may have a wider appeal. The volume is divided into two parts, the first of which is devoted to the study of adult patients and the second to children. The presentation is given largely in a very accessible outline form. It is noteworthy for its simple style and absence of flowery verbiage.

The chapter on "The Art and Practice of the Psychiatric Examination" is especially practical and timely. Specific directions as to how to elicit material of psychiatric interest are given by the authors, together with some warnings and safeguards to be followed by the person conducting the examination. The general impression created is that which is so well known to the trained psychiatrist, namely, that the physician does not tell the patient everything that he knows about him.

Most of the remainder of the section on adults applies principally to the study of psychotic patients. More attention might have been paid to the neurotic group. The first chapter described in the previous paragraph could have been incorporated nicely with the chapter on "Suggestions for Making the Mental Examination."

The greatest value of the work, in the opinion of the reviewer, lies in the portion devoted to the examination of children. The technic of obtaining information from the child by entering his phantasy life is especially interesting and practical. There is considerable material, too, that serves a useful purpose in acquainting medical men with what is considered the most modern advice concerning the emotional needs of childhood. In this respect the book contains more material of a prophylactic or therapeutic nature than purely diagnostic.

In all it may be said that the book would be a valuable addition to the library of every practitioner of medicine.

I C S

The Diagnosis and Treatment of Diseases of the Heart By HENRY A CHRISTIAN M D, Sc D, LL D, Hersey Professor of the Theory and Practice of Physic, Harvard University 373 pages, 15.5 × 24 cm Oxford University Press, New York 1935 Price, \$6.00

Dr Christian writes interestingly and instructively of his experiences in regard to heart disease and its treatment. He emphasizes that the practitioner should as a rule be able to arrive at a cardiac diagnosis without the aids of costly special examinations and that these latter methods should never replace clinical knowledge based on experience. The reviewer has noted that many men of ripe clinical experience arrive at such conclusions, nevertheless he feels that sufficient knowledge is gained at times to make such studies routine in cases of heart disease when practicable. If they serve no other purpose they convince the patient, in these days of public knowledge, that his case has been studied thoroughly. The indications for electrocardiography are discussed in a brief chapter but no detailed description of this subject is offered. There is no chapter on roentgenographic examination of the heart. In the introduction the author states that this book is not written for students nor as a reference work, hence no attempt has been made to make the bibliography complete and it is assumed that the reader has some previous knowledge of the etiology, pathology, etc of heart diseases. Chapters are included on such recent investigations as total ablation of the thyroid in the treatment of heart disease, and the recent advances in the pharmacology of digitalis. In the latter the author finds confirmation of his opinion in regard to the value of tonic doses of digitalis in the treatment of heart disease. The introduction is an essay of itself which may be read with pleasure by everyone.

W S L, JR

The Diagnosis and Treatment of Chronic Diseases of the Respiratory Tract By ELMER H FUNK, M D, and BURGESS GORDON, M D Reprinted from Oxford Monographs on Diagnosis and Treatment 618 pages, 24.5 × 16.5 cm, illustrated Oxford University Press, New York 1936 Price, \$8.00

This volume undertakes to cover the field of chronic pulmonary diseases. The authors have divided it into four main parts. Part one is devoted to a discussion of the general methods of diagnosis, the special diagnostic procedures, such as roentgen-ray bronchography, etc., and the various general and specific therapeutic procedures. Parts two, three and four take up in order diseases of the trachea, bronchi, lungs, pleura, pulmonary tuberculosis, intrathoracic new growths and diseases of the diaphragm.

The manner in which the authors treat the various subjects is briefly as follows: general discussion, etiology, pathology, clinical manifestations, physical signs, diagnosis, and treatment. Along with this are included numerous helpful roentgen-ray plates, a few case histories, and a number of valuable references.

To cover the entire field of the chronic pulmonary diseases in such a thorough and concise manner requires painstaking efforts. The authors have achieved this end admirably and present us with a volume which can be safely recommended as a clear, concise, and valuable text.

Dr Hyman I Goldstein (Associate), Camden, N J, 1 reprint—"Some Historical Notes on Allergy"

At the 84th annual meeting of the North Carolina State Medical Society, Dr Wingate M Johnson (Fellow) of Winston-Salem was installed as President and Dr James B Sidbury (Fellow) of Wilmington was made President-Elect for the coming year

Dr Virgil E Simpson (Fellow), Clinical Professor of Medicine, University of Louisville School of Medicine, delivered the Oration in Medicine at the annual meeting of the Illinois State Medical Association on May 18, 1937

The third annual meeting of the Federation of American Sanatoria (a national association of chest physicians) was held at Atlantic City, N J, June 7 to 11, under the Presidency of Dr William Devitt (Fellow), Allenwood, Pa Dr Edward W Hayes (Fellow), Monrovia, Calif, was installed as the new President Dr Frank Walton Burge (Fellow), Philadelphia, Pa, was Chairman of the Committee on General Arrangements, Dr Clyde M Fish (Fellow), Pleasantville, N J, was Chairman of the Committee on Entertainment The Vice-Presidents of the Federation for the past year included Dr Charles H Cocke (Fellow), Asheville, N C, Dr Louis Mark (Fellow), Columbus, Ohio, Dr George Foster Herben (Fellow), Loomis, N Y, Dr Ralph C Matson (Fellow), Portland, Ore, and Dr Samuel H Watson (Fellow), Tucson, Ariz Dr Charles M Hendricks (Fellow) of El Paso, Texas, is Chairman and Editor-in-Chief of the Federation's journal

At the opening administrative session, addresses were made by Drs Burge Devitt and Hayes Dr J Arthur Myers (Fellow), Minneapolis, Minn, delivered the address at the luncheon meeting on June 7 Dr Marcus W Newcomb (Fellow), Browns Mills, N J, delivered an address on "The Early Diagnosis of Pulmonary Tuberculosis", Dr Frank Walton Burge (Fellow), Philadelphia, delivered an address on "Bronchography" Dr William Egbert Robertson (Fellow), Philadelphia, was a guest speaker at the Banquet at which Dr William C Voorsanger (Fellow) San Francisco, was the toastmaster

Dr Anita M Muhl (Fellow), San Diego, Calif, has recently completed her postgraduate work at Johns Hopkins University and is spending an indefinite period in Europe She will attend the Medical Women's International Association convention at Edinburgh, Scotland, July 12 to 18, and the Second International Congress on Mental Hygiene in Paris, France, the week following

Dr Thomas B Magath (Fellow) of the Mayo Clinic has been appointed Health Officer of the city of Rochester He succeeds Dr Charles H Mayo who has been Health Officer for twenty-five years

The Council on Diabetes of the Public Health Federation, of which Dr Cecil Striker (Fellow) is Chairman, had a "Diabetic Day" with clinics in the morning and a round table luncheon meeting and a meeting of the Academy of Medicine of Cincinnati Dr Russell M Wilder of the Mayo Clinic discussed the medical aspects of diabetes and Dr A W Allen of the Massachusetts General Hospital the surgical aspects

Dr Cecil Striker was guest speaker of the Ohio State Dietetics Association April 13, at Columbus, Ohio, where he spoke on "Newer Concepts in Diabetes"

The Kansas section of the American College of Physicians met at the Menninger Clinic, 3617 West Sixth Avenue, Topeka, Kansas, Thursday, May 20 Dr Thomas

T Holt of Wichita, Governor of the American College of Physicians for Kansas, presided. Members who attended were Dr William H Algie of Kansas City, Kansas, Dr Ralph Ball of Manhattan, Dr James A Butin of Chanute, Dr Arthur Revell of Pittsburg, Dr Harold Jones of Winfield, Dr Harold Palmer of Wichita, Dr George F Corrigan of Wichita, Dr Kenneth L Druet of Salina, Dr Paul M Krall, of Kansas City, Kansas, Dr Fred McEwen of Wichita, Dr Philip Morgan of Emporia, Dr G A Westfall of Halstead, and Dr W C Menninger of Topeka.

Papers given were "Demonstration of Neurological Cases" by Drs Norman Reider and Harry Roback, Topeka. "Psychological Conflicts Expressed in Physical Symptoms Case Studies" by Dr Robert P Knight, Topeka. "Gastrointestinal Neuroses" by Dr W C Menninger, Topeka. "The Clinical Application of Endocrine Therapy" by Dr Ralph Ball, Manhattan. "Undulant Fever" by Dr Wm H Algie, Kansas City, Kansas. "Reports of Some Unusual Cardiac Cases" by Dr Fred McEwen, Wichita. "Some Aspects of a Group of Patients Who Were Examined on the Suspicion of Heart Disease" by Dr Philip Morgan, Emporia. "Impotence and Frigidity" by Dr Karl A Menninger, Topeka.

In addition to the members, many guests attended the program. Out of town guests of the Section included Dr Frank Moorhead of Neodesha, Dr George Seitz of Salina, Dr R R Sheldon of Salina, Dr N P Sherwood of Lawrence, Dr Maurice Snyder of Salina, Dr Charles Underwood of Emporia, Drs Frank Koenig and John Russell of Osawatomie, Dr Earl Vermillion of Salina, Dr M W Husband of Manhattan, Dr Ralph I Canuteson of Lawrence, Dr Henry Benning of Waverly, and Dr Allen Olson of Wichita.

Topeka doctors who attended were Dr R B Stewart, Dr Lucius E Eckles, Dr Leslie Saylor, Dr F A Taggart, Dr J A Crabb, Dr C F Menninger, Dr Robert P Knight, Dr C W Tidd, Dr Norman Reider, Dr Karl A Menninger, Dr C C Carlson, Dr Bernard Kamm, Dr William C Menninger, Dr Martin Grotjahn, Dr H N Roback, Dr Byron L Shifflet, Dr Joseph Pessin, Dr Robert T Morse, and Dr Eugene Eisner.

The program began at ten in the morning and continued all day with a barbecue supper at Indian Hill, Dr Karl Menninger's country home, in the evening.

Dr William Paul Holbrook (Fellow), Tucson, has been elected Vice-President of the Arizona State Medical Association.

Dr Francis G Blake (Fellow and College Governor for Connecticut), Sterling Professor of Medicine, Yale University School of Medicine, was a guest speaker at the annual scientific assembly of the Medical Society of the District of Columbia on May 5 and 6, his subject being "Serum Therapy in Pneumonia." Other members of the College participating on the program were Dr Arthur C Christie (Fellow), Washington, "The Socialization of Medicine To What Extent Is It Desirable?", Dr Walter Freeman (Fellow), Washington, "The Surgical Treatment of Mental Disorders", and Dr Henry B Gwynn (Associate), Washington, "Artificial Fever Therapy of Gonorrheal Arthritis."

Dr Charles Franklin Craig (Fellow), Professor of Tropical Medicine, Tulane University of Louisiana School of Medicine, New Orleans, addressed the eighty-eighth annual session of the Medical Association of Georgia at Macon, May 11 to 14, on "Tropical Diseases of Interest to Southern Physicians."

The seventy-eighth annual session of the Kansas Medical Society was held at Topeka, May 3 to 6. The following Fellows of the College were guest speakers: Dr Elliott P Joslin, Boston, "The Diabetic as a Surgical and an Obstetrical Risk", Dr Archibald L Hoyne, Chicago, "Progress in the Treatment of Meningococcic Meningitis", Dr Russell L Haden, Cleveland, "Clinical Approach to the Rheumatic Problem".

Dr Philip W Brown (Fellow), Rochester, Minn., presented a lecture on "The Management of Diarrheas" before the annual graduate assembly of the Harrisburg (Pa.) Academy of Medicine, May 27.

Sir Frederick G Banting (Fellow), Toronto, Ont., was one of the speakers on the symposium on recent progress in science on the occasion of the dedication of the new building of the Mellon Institute for Industrial Research in Pittsburgh early in May.

Dr William S Middleton (Fellow), Madison, Wis., and Dr Logan Clendenning (Fellow), Kansas City, Mo., presented papers on "William Wood Gerhard" and "The Medical Winning of the West," respectively, before the thirteenth annual meeting of the American Association of the History of Medicine at Atlantic City, N. J., May 3. The meeting commemorated William Wood Gerhard's differentiation of typhus from typhoid one hundred years ago.

Dr Rufus I Cole (Fellow), New York City, addressed the annual Conference of State and Provincial Health Authorities of North America at Washington, D. C., April 5 to 6, on "Possibilities for Pneumonia Control as Indicated by Present Scientific Knowledge".

Dr William H Walsh (Fellow), Chicago, addressed the Tri-State Hospital Assembly, sponsored by the hospital associations of Illinois, Indiana and Wisconsin, at Chicago, May 5 to 7, on "Correct Designing of a Medical Record Library".

Dr Israel Davidsohn (Associate), Chicago, was a speaker at the annual banquet, sponsored by the Chicago Hospital Association, his subject being "Infectious Mononucleosis: Its Hematologic and Serologic Diagnosis".

Dr Rafael Rodriguez Molina (Fellow), San Juan, Puerto Rico, has been elected Secretary of the Puerto Rico chapter of the Pan American Medical Association.

Dr William R Brooksher (Fellow), Fort Smith, Ark., has been reelected Secretary of the Arkansas Medical Society for 1937 to 1938.

Dr George E Wakerlin (Fellow) has been appointed Professor and Head of the Department of Physiology at the University of Illinois College of Medicine, effective September 1. Dr Wakerlin has been Professor of Pharmacology and Physiology at the University of Louisville School of Medicine, Louisville, Ky.

Dr Ralph M Fellows (Fellow), Superintendent of the Osawatomie (Kan.) State Hospital, has been elected Vice-President of the Kansas Society for Mental Hygiene.

Dr Walter C Alvarez (Fellow), Rochester, Minn, addressed the seventieth annual session of the Mississippi State Medical Association at Meridian, Miss, May 11 to 13, on "Helpful Hints in the Diagnosis of Gastro-Intestinal Diseases"

Dr Clarence M Hyland (Fellow), Los Angeles, addressed the Nebraska State Medical Association at Omaha May 10 to 13, on "The Convalescent Serum Center and Its Value to the Community"

Dr Anton J Carlson (Fellow), Chicago spoke upon "Facts and Fallacies of Organotherapy" before the one hundred and forty-sixth annual meeting of the New Hampshire Medical Society at Manchester, May 18 to 19

Dr Meldrum K Wylder (Fellow), Albuquerque, has been appointed a member of the State Board of Public Health of New Mexico

Dr James C Walsh (Associate), Superintendent of the Schenectady (N Y) County Tuberculosis Hospital, has accepted an appointment as Superintendent of the Nassau County Sanatorium at Farmingdale, N Y

Dr Charles A Elliott (Fellow) Chicago, addressed the forty-fifth annual session of the Oklahoma State Medical Association at Tulsa, May 10 to 12, on "Management of Cardiovascular Disease, Management of Hepatic Disease" He also addressed the section on general medicine on "Management of Edema"

The Rhode Island Medical Society sponsored a series of lectures open to the public during the month of March Dr Charles F Gormly (Fellow), Providence, delivered one on the subject "How to Grow Old Gracefully" and Dr Henry L C Weyler (Associate), Providence, gave one on "Why Poison Yourself—The Nostrum Evil"

Dr Edgar A Hines (Fellow), Seneca, has been reelected Secretary of the South Carolina Medical Association for 1937 to 1938

Dr Malcolm T MacEachern (Fellow), Chicago, will address the fifth International Hospital Congress in Paris, July 5 to 12

Dr Harry S Bernton (Fellow), Professor of Hygiene, Georgetown University School of Medicine, Washington, D C, has been appointed clinical specialist in allergy in the bureau of chemistry and soils of the U S Department of Agriculture

Dr Porter P Vinson (Fellow), Richmond, Va, and Dr Charles Sidney Burwell (Fellow), Boston, Mass, were guest speakers on the program of the one hundred and forty-fifth annual meeting of the Connecticut State Medical Society at Bridgeport, May 19 to 20 Dr Vinson spoke on "Diagnosis and Treatment of Primary Malignant Disease of the Tracheobronchial Tree" and Dr Burwell's title was "Factors in the Treatment of Asymptomatic Period of Heart Disease"

Dr William B Castle (Fellow) Boston, and Dr Cyrus C Sturgis (Fellow), Ann Arbor, Mich, were guest speakers at the one hundred and thirty-first annual meeting of the Medical Society of the State of New York at Rochester, May 24 to 26

Dr Louis B McBrayer (Fellow), Southern Pines, has resigned as Secretary and Treasurer of the Medical Society of the State of North Carolina. He has been made honorary Secretary for life. Dr McBrayer served as President of the Medical Society of the State of North Carolina, and had been its Secretary and Treasurer for twenty-one years. The Society, in appreciation of his long service, gave a dinner in his honor, at which a silver service was presented. Dr Paul H Ringer (Fellow), Asheville, was toastmaster.

Dr Edward L Tuohy (Fellow and College Governor for Minnesota), Duluth, addressed the fiftieth annual session of the North Dakota State Medical Association at Grand Forks, May 16 to 18, and was the principal speaker at the annual banquet.

Dr Oscar B Biern (Fellow), Huntington, delivered the annual oration in medicine on "The Value of the Sedimentation Rate in Medicine" at the seventieth annual meeting of the West Virginia State Medical Association at Clarksburg, May 24 to 26. Other guest speakers included Dr Horton R Casparis (Fellow), Nashville, Tenn, "Mental Health of Children, Pediatric Responsibility in Health Education", Dr Louis F Bishop, Jr (Fellow), New York City, "Prevention of Heart Disease, Fugitive Arrhythmias", Dr Moses Paulson (Fellow), Baltimore, "Newer Aspects of Gallbladder Disease of Practical Import", and Dr Thomas Parran (Fellow), Surgeon General, U S Public Health Service, "Public Health Control of Syphilis".

Dr Edward S Sledge (Fellow), Mobile, was elected President of the Medical Association of the State of Alabama on April 22.

Dr John A Sevier (Fellow), Colorado Springs, is President of the Colorado Tuberculosis Association.

Dr William G Herrman (Fellow), Asbury Park, was installed as President of the Medical Society of New Jersey at its annual meeting in Atlantic City April 28.

Dr Rufus I Cole (Fellow), Director of Hospitals of the Rockefeller Institute for Medical Research, New York City, has been announced as the recipient of the George M Kober Medal by the Association of American Physicians for next year.

Dr Cole has announced that he will retire June 30, on account of age, as Director of the Hospital of the Rockefeller Institute for Medical Research. Dr Cole has been Director since 1909. He is a native of Rowsburg, Ohio, took his medical degree at Johns Hopkins University School of Medicine, 1899, and served in various capacities at Johns Hopkins Hospital from 1899 to 1907 and at the medical school from 1901 to 1909. He was President of the Association of American Physicians in 1931. He received the honorary degree of Doctor of Science from the University of Chicago in 1927. He has been a prolific contributor to medical literature and is a member of many national societies.

Dr Walter M Simpson (Fellow), Dayton, Ohio, was made a member of the Legion of Honor of France, in recognition of his research on artificial fever.

Dr Charles E Sears (Fellow), Portland, has been elected President of the Oregon State Medical Society for 1937 to 1938.

Dr William D Stroud (Fellow and Treasurer) was reelected President of the Philadelphia Heart Association, April 28 Dr Samuel A Levine (Fellow), Boston, was a guest speaker at the meeting and Dr David Riesman (Fellow), Philadelphia, as Chairman of the Executive Committee, reviewed the year's work

Dr William S Middleton (Fellow), Madison, Wis , has been appointed Chairman of the Council on Scientific Work of the State Medical Society of Wisconsin This committee supersedes the program committee

Dr William F Lorenz (Fellow), Madison, has been appointed Chairman by Governor La Follette of a " planning council " to develop a program for the control of venereal disease in Wisconsin

Dr Thomas Parran (Fellow), Surgeon General of the U S Public Health Service, gave as his Presidential Address " The Present Needs in the Public Health Control of Gonorrhea " before the American Neisserian Medical Society at Atlantic City, June 8

Under the Presidency of Dr Roy R Kracke (Fellow) Emory University, Ga , the American Society of Clinical Pathologists held its sixteenth annual meeting at Philadelphia, June 2 to 5 Dr Kracke's Presidential Address was on " The Future of Pathology "

Dr Jabez H Elliott (Fellow and College Governor for the Province of Ontario), Toronto, participated in a symposium on the evolution of tuberculosis dispensary control at the thirty-third annual meeting of the National Tuberculosis Association at Milwaukee, Wis , May 31 to June 3

OBITUARIES

DR OTIS SUMTER WARR

Dr Otis S Warr, a Fellow of the College, died in Knoxville, Tennessee, on March 22, 1937, of lobar pneumonia which developed while on a trip through the Great Smoky Mountain National Park

Dr Warr was born in Darlington, South Carolina, April 30, 1881 His preliminary educational advantages were those of the common school of his home community and later he attended the George Peabody College at Nashville, Tennessee He was graduated in medicine from the University of Nashville Medical College in 1907, and following this spent the next four years as intern in several hospitals including Bellevue Hospital in New York

At the conclusion of his internship Dr Warr pursued two years of post-graduate study at Harvard and in Vienna—his work in the latter city being interrupted by the outbreak of the World War On his return home he located in Memphis, Tennessee, where he soon became one of the outstanding internists With the entry of the United States in the World War his application for service in the U S Army was declined on physical grounds but being anxious as always to do his bit he devoted much time to service on one of the medical advisory boards

Early in his career Dr Warr became actively interested in medical organization work He became a Fellow of the College in 1920, was active in the formation of the Mid-South Post-Graduate Assembly held annually in Memphis At the time of his death he was President of the Memphis and Shelby County Medical Society For a number of years he served as Chairman of the Committee on Education of the Tennessee State Medical Association and it was due largely to his vision and energy and effort that the present two year program of Post-Graduate instruction in Obstetrics was provided for the rural practitioner throughout Tennessee

As a physician Dr Warr was outstanding—not only doing a large volume of private and consultation work but doing it unusually capably and well Early in his professional career he became connected with the Medical Department of the University of Tennessee and his ability as a clinical teacher was such that at the time of his death he had risen to the rank of Clinical Professor of Medicine A close student of the problems of diagnosis he was a frequent contributor to medical journals and to the programs of medical societies

But those who had the privilege of knowing Otis Warr will remember him not only as an excellent clinician and teacher but even more as a fine gentleman in whom courage, fairness, loyalty, kindness and sympathy were so outstanding that friendship and association with him were not only real pleasures but inspirations as well

J O MANIER, M D , F A C P ,
Governor for Tennessee

DR ISAAC SURNAMER

Dr Isaac Surnamer (Fellow), 345 Broadway, Paterson, N J, died April 23, 1937, of coronary thrombosis and cerebral hemorrhage, at the age of 64

Dr Surnamer was born in Riga, Latvia, formerly a part of Russia, October 25, 1872. He obtained his preliminary education in the Hildas Heimer Seminary in Berlin, Germany, and graduated from the Gymnasium at Berlin. From Berlin, he entered the Medical Department of the New York University from which he graduated as M D in 1896. In 1903, he took a post-graduate course in the clinics of Germany and in 1916 at Fordham University. He was consulting neurologist and psychologist at the Paterson General Hospital, the Paterson City Hospital and the Valley View Sanatorium for over 30 years, and was serving in that capacity at the time of his death. He was also Lecturer in Neurology at the Paterson General Hospital and the Hackensack General Hospital.

He was a member of the Passaic County Medical Society, the Medical Society of New Jersey, and a Fellow of the American Medical Association.

He was the first President of the Miriam Barnett Free School of Paterson, but was forced to resign several years ago because of declining health.

Dr Surnamer is survived by his wife, Anna Blumberg Surnamer, and two sons, Masso M. and Bertram S. Surnamer.

He was greatly beloved by his community and profession and those who knew him have suffered a great loss in his death.

CLARENCE L. ANDREWS,
Governor for New Jersey

DR EUGENE SMITH DALTON

Dr Eugene Smith Dalton died suddenly on April 19, 1937, of coronary thrombosis, at his home in Brooklyn, N Y, aged 55 years. Besides his wife, Jessie Brown Dalton, he is survived by a son, a daughter and one brother.

Receiving his early education in the public schools of Syracuse, N Y, he later entered Syracuse University and Syracuse Medical School, from which he obtained his medical degree in 1908. While in college, Dr Dalton was outstanding in athletics and an active member of the Psi U and Nu Sigma Nu Fraternities.

After the completion of his medical course, he interned at the City Hospital in New York City, where, under the training of such noteworthy teachers as Edward Janeway, Harlow Brooks, and Evan Evans, he acquired much of the thoughtful professional philosophy which characterized his career. Following this, and a year's residency at the Willard Parker Hospital for Contagious Diseases, he entered the practice of medicine in Brook-

lyn, N Y , devoting his attention almost from the beginning to the problems of internal medicine

Dr Dalton's professional career in Brooklyn could be looked upon as the ideal of medical success His ability and his professional influence grew steadily In his younger years he served as Attending Physician at the Kingston Avenue Hospital (for Contagious Diseases) and in 1916 was appointed Assistant Attending Physician at the Methodist Episcopal Hospital and became Attending Physician at the same institution ten years later Although never a prolific writer, Dr Dalton was an active participant in medical affairs and a ready commentator In addition to being a member of the A M A and the associated county and state societies, he was also a member of the Associated Physicians of Long Island, the Brooklyn Society of Internal Medicine, the American Heart Association and since 1929 a Fellow of the American College of Physicians In addition to his many medical associations, he was a member of the Flatbush Chamber of Commerce and for twenty-five years was an active Mason His favorite recreations consisted of hunting and fishing and, as a member of the Malone Fish and Game Club and the National Rifle Association of America, he was well known as an expert in these diversions

Dr Dalton was looked upon as a physician of unusually sound judgment, exacting and thorough in his methods Beyond this he was a man of broad sympathies, of unflagging devotion to duty and of compelling sincerity and intellectual honesty

The above information has been supplied by Dr Alexis T Mays, F A C P , a former associate of Dr Eugene Smith Dalton

C F TENNEY, M D , F A C P ,
Governor for Eastern New York

ABSTRACT OF THE MINUTES
ANNUAL BUSINESS MEETING
AMERICAN COLLEGE OF PHYSICIANS

ST LOUIS, APRIL 22, 1937

The Annual Business Meeting of the American College of Physicians was held at St Louis, April 22, 1937, with Dr Ernest B Bradley, President, presiding. Abstracted minutes of the preceding Annual Business Meeting held in Detroit, 1936, were read by the Executive Secretary, and by resolution approved.

President Bradley read the following report from the Board of Regents: "It is the feeling of the Regents that the standards for admission to the College should be progressively raised. A change in the By-Laws making certification by the American Board of Internal Medicine a prerequisite to Associateship was considered in recent months by the Board. It was felt, however, that this would at this time constitute too radical an increase in the requirements, and so this proposed amendment has been withdrawn. After further consideration, other proposals for increasing the standards will be submitted to the College.

"Another amendment discontinuing the admission to the College of physicians working in fields allied to internal medicine has likewise been withdrawn by the Regents. It is the present feeling of the Regents that the admission of a certain number of Fellows representing these allied specialties would be desirable. Any application for Fellowship in this class should be scrutinized with especial care and should ultimately require the certification of each candidate by his own special certifying Board or, lacking that, its equivalent in professional or scientific achievement."

Dr William D Stroud, Treasurer, presented the following report, which on resolution, was regularly approved:

TREASURER'S REPORT FOR 1936

"To the Members of the American College of Physicians

As of March 31, 1937, the College has invested securities of a book value amounting to \$101,857 00, of this amount \$58,853 00 is in the Endowment Fund, and \$43,004 00 is in the General Fund, \$82,250 00 or 80.75 per cent of the above amount is invested in bonds, \$4,741 00, or 4.65 per cent, is invested in preferred stocks, and \$14,866 00, or 14.6 per cent, is invested in common stocks. In addition, the College has in bank balances \$47,470 00, making a total of \$149,328 00, as compared with a total of \$157,329 00 approximately one year ago at the time of the last yearly meeting.

"Thus, you see in spite of purchasing our new home for \$52,500 00, and spending \$10,000 00 on furnishings and alterations, our total funds at the present time are only \$8,000 00 less than one year ago."

Mr E R Loveland, the Executive Secretary, made a brief report on the activities of his office, but omitted the statistical data customarily presented because these had been given by the President on the evening of the Convocation. The complete financial statements and auditor's report for 1936 follow these Minutes.

President Bradley, before laying down the gavel of office as President, thanked the members of the College, the Regents and the Governors for their cooperation, help and advice during his term of office

At this point, Dr James H Means of Boston was inducted as President Dr Means spoke at length concerning his aims during the coming year, and bespoke the help and advice of the members everywhere

Dr William Gerry Morgan, Secretary General, on behalf of the College, presented to Dr Ernest B Bradley, retiring President, a silver, engraved ferruled gavel "as a token of the profound appreciation of the rank and file of the College for the masterly way in which you have served as President" The gavel was accepted by Dr Bradley with an expression of appreciation and thanks

President Means, now occupying the chair, called for the report of the Committee on Nominations for 1937, which was presented, as follows, by Dr George Morris Piersol, Chairman

REPORT—COMMITTEE ON NOMINATIONS

For the Year 1937-38

A Nominations for the Elective Offices (already published in the March issue of the ANNALS OF INTERNAL MEDICINE as provided in the By-Laws)

<i>President-Elect</i>	William J Kerr, San Francisco, Calif
<i>First Vice-President</i>	David P Barr, St Louis, Mo
<i>Second Vice-President</i>	G Gill Richards, Salt Lake City, Utah
<i>Third Vice-President</i>	William Gerry Morgan, Washington, D C

B Nominations for the Board of Regents

Term Expiring 1939

Walter L Bierring, Des Moines, Iowa (to fill unexpired term of
Luther F Warren, deceased)

Term Expiring 1940

Ernest B Bradley, Lexington, Ky
Roger I Lee, Boston, Mass
Sydney R Miller, Baltimore, Md
Walter W Palmer, New York, N Y
O H Perry Pepper, Philadelphia, Pa

C Nominations for the Board of Governors

Term Expiring 1938

Francis G Blake, CONNECTICUT, New Haven (to fill unexpired term of
Henry F Stoll, deceased)
Harry L Arnold, HAWAII, Honolulu
John L Calene, SOUTH DAKOTA, Aberdeen

Term Expiring 1939

Hugh A Farris, MARITIME PROVINCES, St John, N B, Can

Term Expiring 1940

Fred W Wilkerson	ALABAMA, Montgomery
Fred G Holmes	ARIZONA, Phoenix
Lewis B Flinn	DELAWARE, Wilmington
Turner Z Cason	FLORIDA, Jacksonville
Glenville Giddings	GEORGIA, Atlanta
James G Carr	Northern ILLINOIS, Chicago
C W Dowden	KENTUCKY, Louisville
Edwin W Gehring	MAINE, Portland
Henry M Thomas, Jr	MARYLAND, Baltimore
G W F Rembert	MISSISSIPPI, Jackson
Louis H Fligman	MONTANA, Helena
LeRoy S Peters	NEW MEXICO, Albuquerque
Charles F Tenney	Eastern NEW YORK, New York
A B Brower	OHIO, Dayton
T Homer Coffen	OREGON, Portland
Charles T Stone	TEXAS, Galveston
Rock Sleyser	WISCONSIN, Wauwatosa
Ramon M Suarez	PUERTO RICO, San Juan
Fred Todd Cadham	MANITOBA, Winnipeg, Can

Respectfully submitted,

Committee on Nominations

WILLIAM B BRIED,
JAMES D BRUCE,
CHARLES T STONE,
CHARLES F MARTIN,
GEORGE MORRIS PIERSON, *Chairman*

After the receipt of the above report, Chairman Means called for nominations from the floor. None were made. Upon motion from the floor, duly seconded and regularly adopted, it was **RESOLVED**, that the nominations be closed whereupon Chairman Means declared all the candidates on the report of the Nominating Committee elected.

Upon motion by Dr C W Dowden, seconded and carried, it was

RESOLVED, that the cordial thanks of the American College of Physicians be extended to the retiring President, Dr Ernest B Bradley, to the General Chairman, Dr David P Barr, and to the members of his committees, individually and collectively, for their faithful work in the preparation and conduct of the St. Louis Session, to the Ladies Entertainment Committee for their efficient and courteous entertainment of the visiting ladies, to the medical schools and hospitals of St. Louis for putting their facilities at the disposal of the College and for their helpful participation, to the Women's Auxiliary of the St. Louis Medical Society for providing automobiles, to the St. Louis Convention Bureau and its Director for their continuous and efficient assistance, and to the Jefferson Hotel and its Convention Manager for their co-operation.

Adjournment

Attest E R LOVELAND,
Executive Secretary

Elections of Secretary General and Treasurer

At a meeting of the Board of Regents at St. Louis on April 23, 1937, Dr. George Morris Piersol of Philadelphia was elected Secretary General, and Dr. William D Stroud of Philadelphia was reelected Treasurer for 1937-38.

EXECUTIVE SECRETARY'S REPORT ON OPERATION

1936

The auditor's report of his examination of the accounts of the College is hereto attached. The statements disclose a continued improvement, as shown by the following:

1932 Surplus	\$ 10,598 08
1933 Surplus	5 801 06
1934 Surplus	16,160 07
1935 Surplus	17,182 09
1936 Surplus	24,948 53

The 1936 surplus was distributed as follows:

Endowment Fund	\$ 3,503 10
General Fund	21,445 43
	<u>\$ 24,948 53</u>

The total principal of the two Funds on December 31, 1936, was

Endowment Fund	\$ 61,784 82
General Fund	119,832 90
	<u>\$181,617 72</u>

One liquidating dividend of \$1,949 29 was received from the Bank of Pittsburgh, reducing the balance now in depositories of banks in hands of receivers to \$6 292 39.

A condensed comparison of income and expenditures for 1934, 1935 and 1936 appears on the following page. Only a Supplement to the 1935 Directory of the College was published during 1936 which accounts for the material decrease in this item over 1935, when a complete Directory was published.

The Executive Offices have been conducted conservatively, with expenditures held to a minimum for effective operation. The budgets for 1937 were approved by the Board of Regents December 13, 1936.

Respectfully submitted,

(Signed) E. R. LOVELAND,
Executive Secretary

Mr E R Loveland, Executive Secretary

Dear Sirs

I have examined the accounts of the

AMERICAN COLLEGE OF PHYSICIANS, INC

for the year ended December 31, 1936, and the accompanying statements, including the Balance Sheet at December 31, 1936, the analyses of the General Fund and the Endowment Fund, and the Detailed Statement of Operations for the year ended December 31, 1936, are in accordance with the books of account and in my opinion set forth correctly the financial position at December 31, 1936, and the results of operations for the calendar year ended December 31 1936, subject to the following comments

Cash The cash was properly accounted for The following is a statement of the cash in the various depositories

Girard Trust Company, Philadelphia	\$11,093 50
Provident Trust Company, Philadelphia	5,661 47
Royal Bank of Canada, Montreal	741 82
Philadelphia Saving Fund Society (Time Deposit)	2,648 37
Western Saving Fund Society (Time Deposit)	2,648 49
	<u>\$22,793 65</u>

The amount of cash in closed banks at January 1, 1936, was \$8,241 68, during the year a liquidating dividend amounting to \$1,949 29 was received, which reduced the amount to \$6,292 39, as shown by the following schedule

	<i>Balance Jan 1, 1936</i>	<i>Liquidating Dividend</i>	<i>Balance Dec 31, 1936</i>
Bank of Pittsburgh, Pittsburgh	\$3,411 26	\$1,949 29	\$1,461 97
Exchange National Bank, Pittsburgh	1,749 20		1,749 20
Highland National Bank, Pittsburgh	3,081 22		3,081 22
	<u>\$8,241 68</u>	<u>\$1,949 29</u>	<u>\$6,292 39</u>

Accounts Receivable The accounts receivable were examined and found to be less than one year old and appear to be good and collectible. The detailed accounts receivable were in agreement with the control account. The amount due from broker of \$2,180 31 represents the proceeds from the sale of 30 Shares of Steel Corporation of Canada, 7 per cent, preferred stock, and was confirmed by correspondence with Hornblower & Weeks. In accordance with the action of the Board of Regents, the amount advanced on account of expenses of the American Board of Internal Medicine has been recorded as an accounts receivable. No requests for confirmation of the other accounts were mailed.

Investments The securities were accounted for by direct correspondence with the Girard Trust Company of Philadelphia and the income for the period under review was verified. It is noted that the uninvested principal and income cash of the Endowment Fund has been segregated from the General Fund cash on the books of account of the College.

General The increase in the amount of the Endowment Fund and the General Fund during the year 1936 is as follows

	<i>Balance Dec 31 1935</i>	<i>Net Increase</i>	<i>Balance Dec 31, 1936</i>
Endowment Fund	\$ 58,281 72	\$ 3,503 10	\$ 61,784 82
General Fund	99,047 47	20,785 43	119,832 90
	<u>\$157,329 19</u>	<u>\$24,288 53</u>	<u>\$181,617 72</u>

In accordance with the instructions of the Executive Secretary, the prepaid insurance at December 31, 1936, was not set up as a deferred expense, the other deferred and accrued items were verified, the charges to the College Headquarters account were examined and included the amount paid for the property at 4200 Pine Street, settlement charges, alteration and improvement costs and other expenses incidental to preparing the property for occupancy, which in my opinion appear to be proper charges to this account, the charges to the Furniture and Equipment accounts represent proper additions to this account and the allowance for depreciation appears to be adequate, it is to be noted that no depreciation has been taken into account on the new equipment purchased for the new headquarters, inasmuch as these purchases occurred principally in November and December, no depreciation reserve has been set up on the new building, and the Executive Secretary has informed me that this problem is receiving the consideration of the Board of Regents, the footings and extensions of the inventory were verified, all ascertainable liabilities have been included in the balance sheet, all recorded receipts from dues, initiation fees, exhibits, advertising, sales of publications, etc., were properly deposited in bank and all disbursements, as indicated by the vouchers, cancelled checks and bank statements, were properly recorded in the books of account.

Very truly yours,

(Signed) H I MACLEAN,
Certified Public Accountant

ANNALS OF INTERNAL MEDICINE

SUBJECT INDEX

Volume 10, 1936-1937

- “**A**BDOMINAL Intermittent Claudication” and Narrowing of the Celiac and Mesenteric Arteries W B SEYMOUR and A A LIEBOW *Case Rep* 1033
- Acidophilus, Lactobacillus—and Its Therapeutic Application L F RETTGER, M N LEVY, L WEINSTEIN and J E WEISS *Rev* 274
- Acute Gummatous Myocarditis Simulating Acute Myocardial Infarction E C REIFENSTEIN *Case Rep* 241
- Acute Pneumonitis W H ALLEN 441
- Address at the Annual Convocation of the American College of Physicians E B BRADLEY 1739
- Adequate Tests of Curative Therapy in Man W D SUTLIFF 89
- Adrenal Cortex, Cushing's Syndrome and Tumors of the— *Edit* 702
- Adrenal Hemorrhage, Fulminating Septicemia Associated with Purpura and Bilateral— (Waterhouse-Friderichsen Syndrome), Report of Two Cases with Review of the Literature M S SACKS 1105
- Allergy of the Nose and Paranasal Sinuses F K HANSEL *Rev* 416
- Amebic Abscess of the Liver, Report of a Case without Previous Manifestations of Amebiasis, Operation and Recovery H L GOLDBURGH *Case Rep* 926
- American Board of Internal Medicine, The— W L BIERRING 1746
- American Board of Internal Medicine, The— *Edit* 411
- American Martyrs to Science Through the Roentgen-Rays P BROWN *Rev* 124
- Amyloidosis, Renal—with Clinical Findings Suggestive of Polycystic Kidney F L JENNINGS, H O ALTNOW and G K HIGGINS *Case Rep* 1398
- Amyloidosis, The Clinical Aspects of— E MOSCHCOWITZ 73
- Anemia, A Case of Pernicious—and Chronic Lymphatic Leukemia M L RICH and L SCHIFF *Case Rep* 252
- Anemia, Occurrence of Macrocytic—in Association with Lesions of the Bowel H R BUTT and C H WATKINS 222
- Anemia, Pernicious—, A Comparison of the Symptoms, Physical and Laboratory Findings of Myxedema and—with a Report of Three Cases J A GREENE 622
- Anemia, Pernicious—Angina Pectoris and—(Old Terminology), a Resume of the Literature, with a Case Report H STALKER 1172
- Anemia, Pernicious—, Variations in Response to Therapy in— L M MOENCH 1115
- Anemia, Pernicious—, The Present Status of—, Experience with 600 Cases over Eight Years C C STURGIS 283
- Angina Pectoris, The Effectiveness of Trichlorethylene in Preventing Attacks of— W S LOVE, JR 1187
- Angina Pectoris and Pernicious Anemia (Old Terminology), a Resume of the Literature, with a Case Report H STALKER 1172
- Angina Pectoris and Syncope, Aortic Stenosis with Special Reference to— A W CONTRATTO and S A LEVINE 1636
- Anniversary Volume in Honor of Dr Joseph Hersey Pratt, The— *Edit* 1727
- Anoxemia in Man, Circulatory Studies on—with Respect to Posture and Carbon Dioxide E GELLHORN 1267
- Anterior Pituitary Body, Discrepancy between Experimental and Clinical Knowledge of the— *Edit* 1901
- Aortic Stenosis with Special Reference to Angina Pectoris and Syncope A W CONTRATTO and S A LEVINE 1636
- Appendicitis, Bradycardia in— Report of a Case M BERNSTEIN and R GOLDSMITH *Case Rep* 1716
- Applied Dietetics for Adults and Child-

- ren in Health and Disease S
BLUM *Rev* 1597
- Arachnodactyly and Status Dysraphicus, A Review R H PINO, E L COOPER and S VAN WIEN 1130
